TAYLOR, J. M., Corinth, Miss.
TRENT, I. N., Columbus, Ohio.
TYSON, JAMES, Philadelphia.

VANDERBECK, C. C., San Francisco, Cal.
VANDERPOEL, EDWARD, New York.
VAN HARLINGEN, ARTHUR, Philadelphia.
VARIAN, WILLIAM, Titusville, Pa.

WARD, STANLEY M., Ellenville, N. Y.
WELLER, E. K., Pottstown, Pa.
WETHERILL, HENRY M., Philadelphia.
WETHERILL, HORACE G., Trenton, N. J.
WHITE, J. WILLIAM, Philadelphia.
WIGHT, J. S., Brooklyn, N. Y.
WILSON, JAMES C., Philadelphia.
WILSON, J. T., Sherman, Texas.
WOLFE, SAMUEL, Skippack, Pa.
WOOD, H. C., Philadelphia.

INDEX.

Abdominal section, three cases, 483.
Abdominal wall, bullet through, 29.
Abortion, management of, 107; prickly ash and, 667.
Abscess, intracranial, 83; abdominal, 158; outside the tonsil, 339; of liver, due to actinomycosis, 350; psoas, 486; of the brain, traumatic subdural, 634; of the lung and empyema, surgery of, 690.
Accident, severe railroad, 525.
Acetate of lead in the treatment of diarrhœa, 363.
Acid, hydrochloric, poisoning with, 61.
Acidity of the contents of the stomach, simple way of testing, 443.
Acne, treatment of, 30; rosacea, morphine as cause of, 264.
Acoustics in physical diagnosis of the chest, 777.
Acrania, 340.
Actinomycosis, abscess of liver due to, 350.
Addison's disease, pathological anatomy of, 784.
Adulteration, 809.
Advice, good, 383.
Ady, A.—Management of new-born child, 109; some new instruments, 330; aseptic needle-forceps, 710.
After-birth in normal labors, treatment of, 252.
Agnew, Cornelius R., 62.
Agnew, D. Hayes.—Laparotomy with excision of a portion of the ileum, 321; the relation of social life to surgical disease, 353.
Air, entrance of into a vein, 336.
Albinos, why they do not see well, 381.
Albuminuria in diabetes mellitus, 602.
Altitude, effects of rapid changes of altitude upon interstitial nephritis, 408.
American Climatological Society, 287.
American dentists in London, 286.
American medical schools in Europe, status of, 512.
American physician, the Emperor and the, 351.
American Rhinological Association, 319.
Ames, L L.—Acetate of lead in the treatment of diarrhœa, 363.
Amputating the wrong leg, 659.
Amputation, modified Pirogoff, 481; at lower third of leg, 482; of metacarpal bones, 482; of wrist joint, 482; of arm, 482; of shoulder-joint, 485; use of relaxation sutures, 609.
Anatomical diagrams, easy method of producing large, 571.
Anders, J. M.—Strangulated hernia; operation and autopsy, 642.
Aneurism, aortic, etiology of, 18; of femoral, 27; of innominate, simultaneous ligation of the right carotid and subclavian arteries, 471; double, of ascending aorta, 591; ligation of superficial femoral artery for, 608; traumatic in a child, 689.
Aneurisms of the aorta, 624.
Angioma of the forehead, 623.
Ankle, resection of, 482.
Ankylostomasia, treatment of with thymol, 714.
Anthrax, case of, 773.
Anthropometry, 127.
Antifebrin, formula for, 191; case of poisoning with, 560, 586; detection of in urine, 586; case of sciatica treated with large doses of, 811.
Antipyretics, influence of upon retention of glycogen, 561.
Antipyrin, antifebrin and phenacetin in phthisis, 164.
Antipyrin, dermatitis due to, 25; in chorea, 212; and its uses, 235; and cocaine in childbirth, 447; in dysmenorrhœa, 542; in chordee, 543; in eye-practice, 601; rashes, 662; in polyuria, 698.
Antisepsis, most satisfactory medium of, 587.
Antiseptic, peroxide of hydrogen as an, 587.
Antiseptic precautions in internal urethrotomy, 382.
Antiseptics, dangers of, 27.
Anus, syphilitic ulcer of, 561.
Aortic regurgitation with aneurism of subclavian artery, 161.
Aphonia, nervous, cured by local use of cocaine, 385.
Apostoli's treatment of fibroids of uterus, 789.
Appendages, see "Uterus."
Appendix and cæcum, cases of disease of, 419.
Appendix, rupture of vermiform, laparotomy, 15.
Apraxia and aphasia, 556.
Army Medical Board, 793.
Arsenic in textile fabrics, 382; bromide of, 676.
Arthritis, rheumatoid, 658; scrofulous, 780.
Ataxia, dissimilarity of the knee-jerks in, 573.
Aulde, John.—Small doses, 102.
Australia, letter from, 504.

Bacillus of whooping-cough, 659.
Baer, B. F.—Recurrent pelvic peritonitis, 449.
Baker, A. R.—Consequences of acute suppuration of middle ear, 259.
Bamberger, H. von, death of, 782.
Barr, G. Walter.—The Signal Service and the physician, 556.
Bashore, Harvey B.—Antipyrine and its uses, 235.
Baum, Charles.—Results of nephrolithotomy and nephrectomy, 387.
Benzoate of sodium, poisoning with, 627.
Bergeon's method, new use for, 624.
Berlin, letter from, 50, 506, 558, 586, 659, 718, 752, 781.
Bile, medicines excreted by, 562.
Biliousness, 568.
Biscuits, medicated, 604.
Bismuth, detection of traces of, 380.
Blackwood, William R. D.—Snake-bites, treatment of, 74; prevention of conception, 394.
Bladder, foreign body in, 211, 276; treatment of rupture of, 218; irritability of, 259; exstrophy of, 338; differential diagnosis of affections of kidneys and, 405; perfected evacuator for removal of *débris* from, 405; stone in, in connection with splenic leucocythæmia, 408; and urethra, rupture of, 486; capillary aspiration of, 811.
Boils, a crop of, 616; treatment of, 727.
Bowel ending in urethra; operation, 408.
Bowels, acute obstruction of, 729.
Brain, double gunshot wound of, 181.
Bright's disease, pathology of, 379.
Broncho-pneumonia, treatment with applications of ice, 308.
Bronchorrhœa, terebene in, 410.
Bronchus, foreign body in, 116.
Brownrigg, John.—Fractures of the forearm, 707.
Buchanan, J. J.—Fractured patella treated by wiring, 399.
Burns, tannic acid in, 446.
Bursa pastoris, 242.

Cactus grandiflorus in heart disease, 444.
Cæsarean section, an unpremeditated, 380, 457.
Caffeine, as a cardiac stimulant, 218; in heart disease, 338.
Calculus, urethral, unusual case of, 408; vesical; secondary pyonephrosis, 486.
California as a sanitarium, 10.
Camphoric acid, 157.
Cancer, two cases of abdominal, 513; curability of, 719; epithelial, of throat and nose, 740.
Capp, William M.—Suggestion and expectancy, 174; a crop of boils, 616.
Carbonic oxide, treatment of poisoning with, 781.
Carcinoma, removal of both testicles for recurrent, 405; of breast, treatment of, 499; latent, of dura mater, 727.
Cardiac complications in rheumatic fever, 592.
Carey, William A.—Epilepsy due to stenosis of os uteri, 169.
Carlsbad salts, artificial, 569.
Carriage, polyclinic, 7.
Castration, accidental, 42.
Cates, B. Brabson.—Operation for strangulated inguino-scrotal hernia, 203.
Catheters, glass, 684.
Centenarian, A, 316.
Cephalhæmatoma, aspiration of, 774.
Cerebral localization in its practical relations, 428; in its surgical relations, 429; in reference to aphasia, 432; surgery, three successful cases of, 464.
Chancres, multiple Hunterian, 378.
Charcot's disease, 11.
Charcot, J. M.—Hysteria and spiritism, 65, 225.
Child, new-born, management of, 109, 579.
Children, an almost unrecognized cause of disease in, 361; prognosis in diseases of respiratory organs in, 367; convulsions in, with special reference to etiology and treatment, 547; sex of, influence of menstrual periods upon, 720; glycerine enemata in, 728; prevention of chronic joint-diseases in, 783.
China grass, 62.
Chloroform, poisoning with, 155; and cocaine anæsthesia combined, 365; pupil as a guide in the administration of, 378; dosage of, 760.
Cholera infantum, 189.
Chordee, antipyrine in, 543.
Chorea, eye in, 17; neurosis allied to, 117; cases of, 147; antipyrine in rheumatic, 212; hereditary, 218; of soft palate, 434; hygienic treatment of, 662.
Choroido-retinitis, an early sign of cerebral syphilis, 811.
Cincinnati polyclinic, 605.
Climate in Graves' disease, 366; and Bright's disease, 422.
Clinics, reports of, 584, 585, 619, 620, 657, 658, 714, 716.
Cocaine, action of, 15; quinsy treated with, 51; -lanoline, 190; use of in oral surgery, 359; and chloroform anæsthesia, 365; local use of in nervous aphonia, 385; and nitrite of amyl, 446; and antipyrine in childbirth, 447.
Codeine, 156; and morphine, comparative value of in diabetes, 415.
Cohen, Solomon Solis.—Treatment of intestinal indigestion, 575.
Cologne, letter from, 534.
Colotomy, 220.
Compression of brain, cerebral localization, 485.
Conception, prevention of, 394, 522, 580, 600, 614, 643, 674, 698, 710, 726, 759.
Concussion of brain, cerebral localization, 484.
Congress, the, and the Journal of the Association, 696.
Conjunctiva, spontaneous hemorrhage from, 12; syphilis of, 14.
Constipation, glycerine suppositories for, 126.
Consultation, enforced, 270.
Consumption, inhalation of heated dry air in, 558; effects of heated damp air in, 558.
Continence, an unpopular prophylactic, 674.
Conversion of mercuric chloride into calomel, 286.
Convulsions in children, with special reference to etiology and treatment, 547; uræmic, following post-scarlatinal nephritis, 560.
Cornea, transplantation of, 25, 72; lead deposits in, 220; treatment of ulcer of, 561; chloride of ethylene and the, 571.
Cornell, new laboratory for, 570.
Corns, removal of subplantar, 810.
Corrosive sublimate poisoning in lying-in women, 436.
Corson, Dr., 26.
Corson, Hiram.—An almost unrecognized cause of disease in young children, 361; our hospitals for the insane poor, 677.
Cough, its significance and treatment, 750.

Country doctor, sketches from note-book of, 269.
Courtesy, professional, 380.
Cowardice, professional, 568.
Cows, vegetable, 636.
Crawford, J. L.—Foreign body in peritoneal cavity, 742.
Crawford, Joel.—Castration, accidental, 42.
Creasote capsules, 383.
Creasote. formulæ for, 543; carbonic acid water a vehicle for, 632; in cancer, 719; creolin a substitute for, 719.
Cremation of filth at Montreal, 604.
Creolin as an intestinal antiseptic, 349; as a mouth-wash and gargle, 382; in eye-practice, 601; a substitute for creasote, 719; 728; experiments with, 792; in obstetric practice, 808; as an antiseptic, 809.
Crime and mental disorders, 534.
Criticism, carping, 478.
Crowley's brain, 572.
Crumpton, H. J.—Sketches from note-book of country doctor, 269.
Curtis, W. H.—Pneumonia and its treatment, 795.
Cutaneous effects of quinine, 294.
Cuts and burns, lanolin in, 28.
Cyst, large sebaceous of scalp, 607; multilocular ovarian, 652; double intra-ligamentary, 653; broad-ligament, 653; intra-ligamentous, 655; treatment of hydatid, 713.
Cystoma, multilocular ovarian, 528.
Cystotomy in hypertrophy of prostate, 155; supra-pubic, 467; intraperitoneal, 723.

Daly, W. H.—Mild measures in the treatment of intra-nasal hypertrophies and inflammations, 612.
Dawson, Byron F.—Neuralgia, 42.
Death, time of, 350.
Deformities of the body, artificial, 534.
DeHart, Madana F.—Continence, an unpopular prophylactic, 674.
Delivery before seventh month, 44.
Dermatitis due to antipyrine, 25.
De Schweinitz, G. E.—Acute unilateral optic neuritis, with the report of a case, 553.
Dewees, William B.—Case of hydrocephalus, 237.
Dextrocardia, case of, 562.
Diabetes, comparative value of codeine and morphine in, 415; insipidus, codeine in, 590; mellitus, albuminuria in, 602; treatment of with large doses of codeine, 690; etiology and treatment of, 712.
Diabetic coma, cause of, 718.
Diabetic gangrene, 775.
Diagnosis, physical, acoustics of the chest in, 777.
Diarrhœa of infants, management of, 78; etiology and treatment of, 79; summer, 154; chronic, treatment of, 157; summer, of children, 209; acetate of lead in treatment of, 363.
Diphtheria, notes on, 316; sudden heart-failure in, 617; pulverized sugar as a remedy in, 782.
Discoveries and inventions, rewards for, 571.
Disease in adults and in children, 668.
Disinfectants that neutralize each other, 444.
Disinfection of bedding and clothing, 95.
Dislocation, reduction of sub-coracoid, 601; of jaw, new treatment for, 636.
Dispensary treatment, fees for, 661.
Doctor, Mr. Depew on the, 94.
Dodge, C. L.—Convulsions in children, with special reference to etiology and treatment, 547.
Dogs, experimental feeding of, 220.
Double vision, significance of, 253.
Drainage, bad, and suits for damages, 374.
Drugs, multiplication of useless, 651.
Drug-stores in Germany, 92.
Dysentery, naphthaline in, 221.
Dysmenorrhœa, treatment of by hypnotism or mental suggestion, 458; antipyrine in the pain of, 542.
Dyspepsia, food and, 105.
Dysphonia, hysterical, 609.

Ear, furuncles in the, 27; consequences of acute suppuration in middle, 259; prevention of disease of by care in childhood, 327; foreign body in, 791.
Eclampsia, pernicious, 13; rare case of, 336.
Ectocardia, congenital, 368.
Ectopia of the heart, rare, 594.
Edinburgh, epidemic of sore throat, 16.
EDITORIALS:
Antiseptic midwifery in private practice, 282.
Appendages, uterine, indications for the removal of, 149.
Artificial food for infants, 412.
Baby farms, 215.
Bed-room, air of, 509.
Body, claims of the, 565.
Cæsarean section, 56.
Carbonic acid, inhalations of in dyspnœa, 630.
Chemical analysis, abuse of, 537.
Child-birth after excision of the rectum, 788.
Children, danger to, 88.
Chloroform as an anæsthetic, 87.
Chyluria, 596.
Colotomy, a detail of, 89.
Congress for the study of tuberculosis, 311.
Congress of American physicians and surgeons, 369.
Contagion by respiration, 150.
Crooked way, 186.
Cruelty of cowardice, 439.
Cystotomy, intraperitoneal, 723.
Decision, an important, 786.
Editorial labors, 246.
Epistaxis and interstitial nephritis, 152.
Etiology of summer diarrhœas in infants, 245.
Explanation, 121.
Faith cure, 313.
Family Doctor Society, 248.
Fault in medical journals, 440.
Feces, incontinence of, 20.
Folly which is almost a crime, 277.
Food adulteration, 787.
Fractures at the elbow-joint, treatment of, 722.
French critic on an English writer, 121.
Glycerine suppositories for constipation, 185.
Hæmoptysis, iodoform in, 22.
Heat fever, treatment of, 90.
Homœopathic State Medical Society, 440.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

College of Physicians and Surgeons

OF BALTIMORE, MD.

The Preliminary Course begins September 15th, 1888.

The Regular Session will open October 1st, 1888, and close about March 1st, 1889.

Attendance upon two full sessions is required for graduation.

The Clinical facilities of this school will be further increased by the new "City Hospital," which has a capacity of 300 beds.

For Catalogue, containing full information as to fees, etc., write to

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers, with Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

THE

College of Physicians and Surgeons

OF CHICAGO.

Seventh Regular Session opens Sept. 25, 1888.

AN EPIDEMIC OF MALIGNANT TYPHOID FEVER AT LOSANTVILLE, IND.

I. N. TRENT, M.D.,
COLUMBUS, O.

On June 30, 1887, the first recognized case of typhoid that had occurred in our practice for a long series of months presented itself. After this until January 1, 1888, our village and the surrounding country were almost depopulated by it. I say the first recognized case, for I am persuaded that some months before there was a case of typhoid in the village, which was masked by complications and ran its course to convalescence without being diagnosticated. Of course no attempt was made toward disinfecting the stools, which were thrown into the abominable privy-vault with which our village was cursed. No well in the town is more than fifty feet from one or more of these vaults, and some of them are within fifteen or twenty feet. The micrococci from this unrecognized case multiplied and flourished in this vault, and a few strayed away to the neighboring well. There they lived till after a very protracted drought, in which the water in the wells became so low that we had to drink all the impurities of the water in a concentrated form—bacteria and all. It was simply the essence of nastiness boiled down. Then it was that our epidemic began. Had we been able to control our patients, we might have stopped it soon. But the people there are like many people elsewhere: they believe disease is a sort of providential something, they don't know what, and don't care what, and that it cannot be prevented. Hence our efforts at complete disinfection were only partly successful. One uncontrollable patient insisted that, as long as he was able to turn out and walk, he would not have anyone carrying the chamber after him. He would boldly walk out, attend to the calls of nature, and return to bed. Fortunately such cases were few. As people became more in earnest and more careful, and as deeper wells were sunk, and the rains came to dilute the nastiness so that in a given amount of the water we did not get as much of the filth—and probably what was best of all, as many began to use rain-water or boiled water—then the epidemic began to subside. The writer of this paper was the last patient, and he took to his bed on New Year's day.

Losantville was then only a small village of one hundred and sixty inhabitants; but out of these hundred and sixty there were thirty stricken down, of whom four died. All told, the writer saw fifty-six cases, having full control of thirty-seven of this number, while the other nineteen were either seen in consultation or treated by other physicians. Out of the 56 there were 12 deaths—a high rate of mortality, 21.4 per cent. Seven cases were seen but once or twice, and five of these died. So it is but fair to count the mortality as 7 in 49, or 14.2 per cent. The case running the shortest course lasted fifteen days. The patient was a woman, and she seemed to be completely overwhelmed from the very beginning with a large dose of the poison, and steadily and rapidly sank, dying of heart-failure, but without complications. Her pulse gradually increased from 108 to 150. Her temperature ranged from 101° to 104°.

The longest continued case ran twenty weeks from the beginning of the fever till he became sufficiently convalescent to stand alone. This case began as an intermittent, then became remittent in type, and finally continuous. At no time did his fever run high, but it continued uninterruptedly for the whole five months. During the last six or eight weeks of his illness he had involuntary alvine evacuations, and his delirium continued for several weeks after he was up and around. Complications were present in fifteen of the cases. One patient had an abscess in both middle ears, a large bed-sore, and involuntary evacuations from the bowels for eight weeks, but finally recovered. Five had intestinal hemorrhage. Three of these patients died. One patient, after his disease had run a smooth course, and after he was convalescent for a week, was attacked with severe colic and gastro-enteritis, which kept up irregularly for six weeks. One became markedly jaundiced; one had broncho-pneumonia; two had phlebitis, in one of which both limbs suppurated; three had bed-sores—in one which resulted fatally the bed-sore was the largest and most intractable I ever saw. As I was disappointed in nurses one night, a son was left, who was himself just recovering from a severe attack, to watch with his mother. A frequent and distressing desire to urinate seized the mother. The son, not being able to place the bed-pan so often, padded it as best he could, and left it in place for several hours. The result was breaking down of all that part which was pressed upon. A slough came away, leaving a hole four inches in diameter, extending down to the sacrum and coccyx, exposing all their processes and ligaments. The origin of the glutei muscles and their coarse fibres were as plain as ever I saw in the dissecting-room. After this, one sore appeared after another, till at least twenty were on her back. Cold abscesses began to form, and death closed the scene. To illustrate how slight pressure on her would cause a sore, it may be mentioned that she was inclined to lie with one hand to her face so that the tips of her fingers touched her cheek. A bed-sore formed here, and was followed by sloughing down to the buccinator muscle.

Two patients had endocarditis, and one of them died; one developed a melancholic condition, in which hysterical lock-jaw, etc., played a prominent part. Four had involuntary discharges; and two of these patients died. The eruption occurred about the tenth day, and in a few cases was so profuse as to resemble measles at a superficial glance. Two patients had relapses which occurred after an absence of fever for ten days. I generally found them free from fever in the morning for a few days about the end of the third week.

In closely watching these cases with a deep interest in the disease, I became convinced of the following practical points:

1. The early diagnosis of typhoid fever is impossible. 2. Different epidemics differ greatly in severity. 3. One attack affords but slight protection against another. 4. Epistaxis and diarrhœa, as early symptoms, are exceptions. 5. In a great majority of cases, the disease is ushered in by a chill. 6. The mortality is greatest among people in good financial condition. 7. Height of temperature is an uncertain guide as to the final termination. 8. Hemorrhage does not occur oftenest when the fever runs high. 9. The disease is strictly self-limited. 10. Digitalis is utterly useless in controlling the heart. 11. Strict antisepsis will prevent a spread of the disease—it is not contagious.

To dilate a little further on the summary of my observations, I would say, to prove that the early diagnosis of typhoid is impossible, I have but to appeal to every practitioner of many years' standing. He will tell me that often what he unhesitatingly pronounced typhoid ended in three or four days, and what he insisted was nothing but malaria proved to be typhoid in all its dreadfulness. I was called to see a girl ten years old, who had complained for two weeks, with a gradually increasing fever for six days. I found her with pulse 124, temperature 105°, bowels tympanitic and very tender; repeated epistaxis, a severe frontal headache, a peculiar muddy appearance of the skin. This happening in the midst of the epidemic, I pronounced the disease typhoid at the first visit—a thing I very seldom do. The child was in school in less than a week. Such cases as this were of frequent occurrence.

Before this epidemic, we had, in six years treated forty-four cases, all told, with two deaths—a mortality of four and a half per cent. In this epidemic it was 14 per cent. Quite a number who had undoubted typhoid say they had had it before. Of course we must take into account the possibility of a mistaken diagnosis. Several years ago I became convinced that epistaxis was not the rule, and have wondered why authors and lecturers so persistently set this down as a symptom. In all the cases during the epidemic, but one gave me a history of nose-

bleed at the first visit, and in but one or two did it occur after the first visit.

I think I may safely say that 85 per cent. of the cases were ushered in by a chill. Some had a single chill, others two, and others as many as five occurring at regular intervals. True, we were in a malarious country, and it is probable that latent malaria develops itself when the system becomes reduced by the incipient typhoid, thus masking the latter. Hence our misnomer — typho-malarial. I have seen the disease in all grades of society, but never saw but one death among the lowly. I have seen them recover amid squalor, filth, and negligence, and they die oftenest when surrounded with luxury and all that we as physicians can ask in the way of nursing. Hence I say the mortality is greatest among people who are in good financial condition. One physician suggested an explanation of this fact by saying that probably in our anxiety to save the good-paying patient we do too much. His inference was that the more severely we leave these cases alone the better they get along. I cannot plead guilty to discriminating between the classes, neither am I guilty of over-dosage.

As to prognosis, I regard the height of the temperature as of very uncertain value, while the rapidity of the pulse is the best guide we have. A pulse continuing over 100 for many days is a bad omen, and calls for something—not digitalis—to control it. I thus speak of digitalis from my personal experience. I have given it time and time again, and I find that I get *no* results till the effects come in such overwhelming quantity that I wish I had given nature still another chance. For instance, a young woman was having a pulse day after day of 108. I began giving tincture of digitalis, increasing it each day, for the pulse gradually went up, till she took two drachms each day. Finally, one evening her pulse was 120. I again increased the digitalis. Next morning it was 75 and slightly irregular. That evening it was 47 and very irregular. I stopped the drug when the pulse went to 75, but it went on down to 42, and became so irregular both in time and force that the normal heart-sounds were indistinguishable. It continued thus for two weeks, and then went up to 108. Patient recovered. This did not occur in one patient alone, but the experience was repeated each time I pushed the digitalis.

Before this epidemic, I had treated several cases that were complicated with intestinal hemorrhage, and all recovered. I began to think with Flint that if it had any influence in the prognosis it made it more favorable. But in this epidemic the first three cases of hemorrhage died. Then I began to think that hemorrhage increased the danger about one hundred times. The fatal cases of hemorrhage occurred in cases that had previously been noted for a low temperature—not for a high temperature, as is stated by most authors.

The popular belief that it is a contagious disease still survives in the prejudices of those who do not make it a study. The people of our village will tolerate any number of cases of intermittent or remittent, or pneumonia, or rheumatism, in the same family at the same time, without believing them contagious. But let even two cases of typhoid occur in the same family, and they are for ever afterward cited as evidence of the contagiousness of the disease. I had abundant evidence during this epidemic to fully convince me of the non-contagiousness and the mere infectiousness of the disease. In those families in which disinfection was least observed, the greatest number of cases occurred, while in those families in which we had full control of the disinfecting, or rather our orders for disinfecting were fully carried out, but one case occurred.

We had no stereotyped course of treatment, but met each case as it presented itself. I think we got good results in controlling the diarrhœa with naphthaline. Antifebrine in most cases added to the comfort of the patient if given when the temperature was high, but if pushed it invariably caused depression, cold extremities, with general shivering.

REPORT OF A CASE OF FECAL ACCUMULATION AND CONSEQUENT OBSTRUCTION FOLLOWING LAPAROTOMY.

BY CHARLES B. PENROSE, PH.D., M.D.,
PHILADELPHIA.

The following case is reported because it serves to illustrate the danger of permitting the bowels to become constipated immediately after an intra-peritoneal operation. F. L., aged 35. A small, weak, anæmic woman, with lateral spinal curvature and deformed pelvis. Had one child three years ago at seven months, premature labor having been induced by Dr. Bernardy, on account of the pelvic deformity.

She was operated upon by the writer at the Gynecean Hospital, February 18, 1888,

for the removal of a small ovarian cyst on the right side.

The operation was simple, and the convalescence very easy. The bowels were moved by enema on the third day, and after that regularly every one or two days, until the fifteenth day after operation, when she was allowed to get out of bed, and ceased to be under strict medical supervision. She then became constipated, and neglected to call the attention of the nurse or medical attendant to the condition of her bowels until eight days had passed without her having an evacuation.

She then presented the following symptoms: Tongue pasty, white on edges, black in centre; pulse 120; temperature 101°. There was continual nausea and occasional vomiting. She suffered from attacks of tenesmus following the discharge, by rectum, of small quantities of blood-streaked mucus. No feces were passed. There was very slight abdominal distension and tympany, and no general abdominal pain. Lying immediately under the parietes and to the right of the scar of the abdominal incision was a very tender movable mass, about the size of a child's head. The consistency of the mass could not be determined by palpation on account of the great tenderness.

The diagnosis of fecal impaction, probably in a mass of adherent intestines, was made, and she was treated with frequently repeated small doses of calomel and large rectal injections of warm water administered in the knee-chest position. During the first two days of this treatment, many small hard lumps of feces were discharged, and the abdominal tumor became less tender and diminished in size. The discharge of mucus, and the tenesmus also diminished. On the third day, the bowels began to move of themselves, there being six or eight large naturally formed movements daily for three or four days. The abdominal tumor rapidly decreased in size, and had disappeared by the eighth day after it had first been observed.

The further convalescence was uneventful.

The tendency to constipation, accumulation of feces, and consequent intestinal obstruction, which follows laparotomy, and which was so marked in the case just recorded, is in most instances due to slight peritoneal adhesions which occur between loops of intestine. These adhesions, by matting together segments of bowel, not only interfere with proper peristaltic motion, but also favor the production of sharp flexures or kinks, which seriously impede the flow of the intestinal contents.

In most cases of abdominal section, few, if any, intestinal adhesions occur. The most frequent position of these adhesions is along the line of incision, or to the pedicle of a tumor. Adhesions to the incision are, to a great extent, excluded if the omentum is swept well down before closing the abdominal wound; and, if the bowels are kept freely moved from the second or third day after operation, any adhesions which have formed, either to the abdominal wound or between loops of intestine, will probably be broken up.

In other cases of abdominal section, however, where there has been much exposure or irritation of the peritoneum, some local, if not general, adhesive peritonitis is very common, and the consequent matting together of loops of intestine is the cause of subsequent trouble. The practice of free abdominal irrigation before closing the incision in such cases does much toward preventing these adhesions. But, after this irrigation, the usual procedure of sponging dry the peritoneum is to be avoided.

Such sponging is not only unnecessary, but it is often deleterious; the irritated peritoneal surfaces being more likely to adhere when dry and in close contact, than when surrounded by an unirritating fluid. For this reason, it is best in such cases to make no final sponging, but to leave a quantity of clean water in the abdomen when the incision is closed. The quantity of water which can be thus left depends altogether upon the rigidity of the parietes and the condition of the intestines as regards distension.

In all cases, the early administration of purgatives, and their continued use, if necessary after the patient is out of bed, will tend to prevent and to overcome this form of intestinal obstruction, which is not an uncommon sequel of laparotomy.

CASE OF FECAL ABSCESS.

BY A. NOEL SMITH, M.D.,
DOVER, N. H.

There is perhaps no region of the body in which diagnosis is more difficult than it is in certain parts covered by the abdominal parietes. In the inguinal region, for example, how many surgeons have made false steps, where so much depends upon an early and correct diagnosis, in order that suitable treatment may be inaugurated. We some-

times see a case presenting quite an enlargement in the neighborhood of Poupart's ligament. To listen to some surgeons and surgical writers, we might be led to believe it easy to distinguish between femoral and inguinal hernias; but in *practice*, a mistake is quite often made. So, then, if we diagnosticate hernia, we have yet to say whether it is femoral or inguinal. But then we also get here "enlarged and inflamed glands, which may be attended with symptoms of disturbance of the alimentary canal, so as to simulate hernial conditions."

Again, there may be a deeply seated abscess pointing in this region. Thus it is we often meet with obscure cases in practice which give us much anxiety, until lapse of time and absence of peculiar symptoms exclude the graver conditions of hernias, etc.

Abscesses forming in the *right* iliac region, as the result of a foreign body in the appendix vermiformis, are not very rare. We have all seen cases recorded, if we have not met them in our professional life, of patients who presented symptoms of hernia, and who finally had abscesses form in the right iliac region, from which cherry-stones or other foreign bodies were discharged.

But it is seldom the case that we find foreign bodies lodged in any other part of the large bowel, which at length lead to perforation, and the formation of abscesses. One author states: "There are three conditions under which a foreign body which has passed through the length of the alimentary canal may become retained in the colon, sigmoid flexure, or rectum. These are (1) when solid fecal matter is deposited around the foreign body; (2) when owing to its shape the foreign body sticks into the wall of the gut, or becomes fixed across its lumen; and (3) when any constriction of the bowel exists."

Whenever fecal abscess occurs, one of two things is true: either the fecal matter has passed through an opening in the bowel, and by its irritating presence set up the surrounding inflammatory action, or the abscess was originally formed outside the gut, and has ulcerated through into the intestine. Thus the fecal element in the case is somewhat of the nature of an accident, just as, to quote another, "the opening of an abscess into an artery, vein, or joint is an accidental complication."

The causes of fecal abscess will readily suggest themselves. Cancer is considered the most common of all causes, and, after this, on the right side, diseases of the vermiform appendix. Ulcers of the bowel may prove a cause, whether simple or tubercular in their nature. Gall-stones may sometimes ulcerate through; and then, as already intimated, foreign bodies may by their confined presence press through the walls, and a circumscribed inflammation with abscess result.

I will at this point note a case occurring in my practice in the early autumn of 1887. My patient was an unmarried woman about sixty years old. Her previous history was excellent. I was called to see her September 19, 1887. She had noticed for two days an enlargement and tenderness in the left inguinal region. I found upon examination the swelling, as described, quite large, hard throughout its extent, and not movable. The patient's bowels were constipated.

I could not arrive at a diagnosis, but deemed it one of three things: inguinal hernia, femoral hernia, or abscess. My opinion inclined to the latter. I gave calcium sulphide, gr. 1-10, every hour, and used locally an ointment composed of fluid extract of belladonna and agnine.

September 20. — Patient no better. Slight movement of bowels from enemata. Same treatment continued. I did not think it a case of hernia, because there was no nausea, vomiting, pain about the navel, nor any other symptom of hernia.

September 21.—Patient had three spontaneous movements of bowels, relieving anxiety as regarded strangulated hernia. As there was with me now no doubt of abscess, I began to poultice, giving quinine in tonic doses, and morphia with atropia, to relieve pain and secure rest. Also ordered milk diet. There was no particular change for some days, the parts growing gradually redder and more discolored. On September 28, there was quite marked bulging, but the swelling was tense. The next day, the tumor was softer in places; but I could not detect fluctuation. On September 30, it was more tense, if anything, and the bulging was more marked.

On October 1, I made an incision through the skin in the centre of the tumor, just above Poupart's ligament, after injecting cocaine. I inserted dressing-forceps in the wound, and separated the blades, after Hilton's method. Upon doing so, to my surprise, quite a quantity of fetid gas escaped with force sufficient to spray the blood from the opening, and with quite a sharp report, which startled the patient.

The tumor, which had extended upward to the crest of the ilium, was now a trifle less tense, and I got crepitation.

At my evening visit, I again dilated the opening with the forceps, and a dark, feculent, very offensive discharge followed. I continued poulticing through the next day, when I enlarged the opening and irrigated the cavity well with a wash of corrosive sublimate (1–10,000), inserting a rubber drainage-tube. There was now no change in discharge, which was just as feculent as before. There was a natural movement of bowels at this time, with a slight admixture of abscess material. Up to the day of opening the abscess, the temperature ranged from 100° to 102° F., and the pulse from 90 to 100. On the third day after, there was no pain, and in the morning the temperature was 99°, the pulse 84, while at 6 P.M. the temperature was 101°, and the pulse 100, and the patient was taking nourishment well.

On October 14, after ten days during which the wound cleared up somewhat, the pulse was 104, the temperature 99½°. There was on this day a movement of the bowels, and a large fecal discharge from the wound. The next day, there was no fecal matter in the discharge; the patient felt pretty well, and the wound looked better. I now ordered an enema to be given daily to keep the rectum and the lower portion of the colon free, and strictly enjoined the recumbent dorsal position. From this time on, the patient gradually improved, no more feces being discharged through the abscess wound, and regular movements of the bowels being secured by means of injections. I made my last visit November 18, and found the fistulous openings nearly closed. The patient was soon after fully recovered, and she remains, at this writing, June 1, 1888, in a healthy condition.

Now what was the cause of the abscess in this case? And what was the cause of the fecal complication?

In the management of the case, I found no foreign body in the discharges, although of course one may have been present and escaped notice. Had the abscess been located in the *right* inguinal region, over the site of the cæcum, I should have regarded the deposit of some substance in the appendix as the exciting cause. And, although I had no positive evidence of the presence of a foreign body, I am rather inclined to the opinion that some foreign substance *was* the cause of the abscess, as most other causes were eliminated by the process of exclusion. It seems to me, moreover, that the point at which perforation took place must have been the sigmoid flexure of the colon; because of its situation, and because of the large quantity of feces which was discharged from the wound on October 14. This discharge was characteristic of the contents of the colon; indeed, it would have passed well for the usual evacuation from the rectum. Certainly it would have been impossible to have obtained such matter from the small intestine. Taking into consideration the situation of the abscess, as also its character, the case seemed to me of sufficient interest to report.

Then the patient was very fortunate in being able to make so speedy and complete a recovery. Usually in such cases, if full restoration to health takes place, convalescence is tardy and is attended with much inconvenience and discomfort. A case is on record, I am well aware, in which a woman had an abscess opened in the left groin, and eighty ounces of feces came away through the incision, and a very speedy recovery ensued. But this is exceptional. The reporter of the case says: "The above is the only instance we remember in which, some days after the opening of an abscess in the loin, the contents of the intestine came away through the wound, and then the opening in the gut closed completely and permanently, and the patient recovered entirely in three weeks."

I find another case, recorded by a Dr. Thurman, the cause of death clearly determining the cause of the abscess. This abscess formed over the transverse colon, pointing just below the umbilicus. When it was opened, as in my own case, "gas and fetid feculent matter escaped, pus and coagula being mixed with the feces." This patient died soon afterward, of cancer.

The prognosis in abscesses of the abdomen is more unfavorable when they become fecal in character, and they are more or less grave, of course, in accordance with their location.

The treatment of fecal abscess should be conducted upon general and well-established principles, varied only to meet the peculiar requirements of each case. Very active surgical interference is advocated by some, among whom is Mr. Lawson Tait, who thinks that no case should be allowed to run for any length of time after feces have been discovered mixed with the pus. He thinks that the abdomen ought to be opened immediately, and the source of the trouble ascertained and removed. He does not fear interference with the peritoneum. But, unfortunately for both ourselves and our patients, we are not all so confident.

RUPTURE OF STOMACH FROM EXTERNAL VIOLENCE. DEATH IN TWELVE HOURS.

BY O. C. STRICKLER, M.D.,
NEW ULM, MINNESOTA.

On April 21, I was called to see J. M., 65 years old, German, who, while splitting wood a short time before, had accidentally struck himself on the stomach with the handle of an axe. I found a somewhat feeble-looking old man lying in bed in a semi-recumbent position, complaining of very severe gastric and abdominal pain, and in a very weak and collapsed condition.

On inquiry, I found that the patient had suffered with an acute gastric disorder six years before, since which time he had been in quite delicate health, with a difficulty in digesting coarse food. The patient stated that at the time of the injury he felt a sensation as of something tearing in his stomach, and immediately afterward was seized with severe burning pain in the abdomen. This, with the general collapsed condition of the patient, led me to make a diagnosis of rupture of the stomach, and, on account of the opposition to any operative interference, a positively fatal prognosis.

The wife of the unfortunate man laughed at the idea of anything serious resulting from so simple an injury, especially as since his former illness he had had frequent attacks of gastric disorder of a painful nature, and in all he had recovered without medical aid. I explained what in my opinion was the nature of the injury and the inevitably fatal result without operation, but without producing any effect.

I prescribed morphia to relieve the terrible sufferings, and with so much relief that the friends again doubted the correctness of the diagnosis; but in a few hours the symptoms again became grave, vomiting ensued, and death occurred in about twelve hours from the reception of the injury.

At the *post-mortem*, six hours after death, rigor mortis was well developed; nothing else external is worthy of note. Dr. L. A. Fritsche kindly consented to perform the dissection. On opening the peritoneal cavity, a large amount of greenish fluid was seen, with shreds of mucous tissue, showing that the supposition of rupture in some portion of the alimentary canal had been correct. The great omentum presented a very congested appearance, and on further examination a rupture of its substance, sufficiently large to admit a finger, was discovered. After close search and inflation of the stomach, a rupture in the smaller curvature near the pyloric orifice was found.

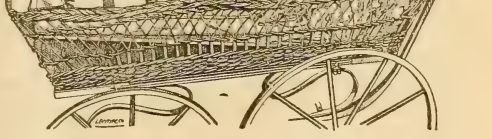
No malignant disease was found in the stomach or other abdominal organs, but, from the appearance of the gastric mucous membrane, I am led to believe that the trouble from which the patient had suffered six years before was of an ulcerous nature, with subsequent gastritis, as points resembling cicatrices were discovered near the pyloric orifice.

I do not think, considering the condition of the stomach *post mortem*, that, had the friends consented to an operation, the result would have been different; and yet this was the only resort offering the possibility of recovery. It is certainly peculiar that a person in so feeble a condition before the accident could so long withstand the severe pain and shock necessarily following so serious an injury.

"POLYCLINIC CARRIAGE" FOR EXTENSION AND COUNTER-EXTENSION.

BY A. B. HIRSH, M.D.,
ADJUNCT PROFESSOR OF ORTHOPÆDIC SURGERY, POLYCLINIC, PHILADELPHIA.

This simple apparatus is designed to keep up continuous traction—therefore, rest—whilst permitting an out-of-door atmosphere. Its first occupant was a stout two-year-old boy, of the flaxen-haired strumous type, the subject of incipient coxalgia.



The value of complete rest in bed, in this disease, and the difficulty, frequently met in practice, of obtaining good hygienic surroundings in so many homes, especially in the stifling city summer season, are familiar facts; so this "carriage" was planned to meet these objects.

Reference to the cut shows an ordinary wickerwork perambulator, the body of which has been lengthened to fit the size of the patient, by dividing vertically and exactly in the middle, the head and foot pieces, which are then straightened out and a new bottom

made—neat wooden painted boards being inserted to fill the spaces at each end. Inside the entire length of the bottom of the body is placed an inclined plane of very light pine board, which rests in front on a block some two inches high and is covered by a light hair mattress and pillow.

The ordinary adhesive strap and stirrup apparatus having been applied on the limb up to the hip (in this case the left one), a cord is fastened to the stirrup, passing through two screw-eyes in the footboard, one opposite the instep and the other at the right-hand angle. Then the cord passes backward to a heavy rubber band attached to a hook screwed into the headboard, alongside and above the child—a weight of three to five pounds being gained by the band's being lengthened twelve to fifteen inches. Any increase of traction can be made by simply further stretching this band, originally intended for closing the opened door.

It was my intention to pass the cord from the stirrup through the footboard and under the body of the carriage, so as to attach a weight; but it is to Dr. H. Augustus Wilson I must acknowledge heartiest thanks for the suggestion of the screw-eyes and rubber band. His improvement, besides simplifying the apparatus and making it more sightly, lies in the important fact that by its use he prevents the otherwise unavoidably painful jarring which is made in passing over gutters and all other uneven surfaces.

In a similar coach since made, I obtained a greater inclination backward by simply screwing a hook underneath the body and fastening another heavy rubber band from it around the rear axle.

The idea can of course be elaborated for more fastidious patients, as the parts needed for the coach are supplied in Philadelphia by Gustavus A. Gefvert, orthopædic mechanist, 250 North Fifteenth Street, and Messrs. Charles Lentz & Sons, 18 North Eleventh Street.

2130 Master Street.

PATENT MEDICINE MAN (to editor)—"You made a nice mess of that testimonial advertisement." *Editor*—"How?" *Patent Medicine Man*—"John Smith wrote: 'Your Live Forever Pellets are doing me a great deal of good. Send me another box;' and I told you to give it a prominent place." *Editor*—"I did—immediately preceding the death-notices." *Patent Medicine Man*—"Yes, and the first death-notice on the list was that of John Smith!"—*Tid-Bits.*

SOCIETY REPORTS.

NEW YORK SOCIETY OF MEDICAL JURISPRUDENCE AND STATE MEDICINE.

Stated Meeting, June 15, 1888.

The Ethics of Opium Habitués.

DR. J. B. MATTISON, of Brooklyn, read the first paper. It was a common opinion, he said, that all opium habitués were liars. He had long held that this view was a mistaken one. In the ranks of these unfortunates, there were some who scorned deceit. His answer to the question Why do men take opium? was that which had been given by an eminent physician many years ago: They took it for a physical necessity. His remarks applied, he said, only to the better class of opium habitués, who, in nearly all instances, had commenced the habit because of a painful disorder of the body or mind. The drug was very commonly first prescribed by a physician who failed too often to place sufficient safeguards around its use, and to warn the patient against its dangers. Granting a painful physical necessity, and the daily or semi-daily use of the drug for weeks or months, and there were very few who could withstand its power. He had seen a man who had faced the cold and hardships of an Arctic expedition, succumb to the influence of opium in four weeks. It was a very common belief that the opium habit was due generally to a vicious tendency, and the subjects of it were ostracized from good society. Thus, when they lied regarding their habit, it was due to the principle of self-protection. But, notwithstanding the disgrace which they would rest under should their habit become known, there were many who refused to take refuge behind the subterfuge of a lie justified through self-protection. He had often found opium habitués who were strict followers of the truth. The commonly accepted view that these people were victims to their own wrong-doing prevented the adoption of correct treatment and led the patients themselves to regard their condition as hopeless. He read part of a letter from a woman who had been cured of the habit, telling of the great difficulty she had experienced in convincing her old neighbors that she had ceased the use of the drug.

DR. MCLAURY'S experience had been that the use of opium had a decided tendency to lower the moral tone and also the judgment

of its victims. He thought the drug had a worse effect in that respect than in any other.

Dr. E. C. Spitzka said it was the first time in his experience that, in the discussion of a medical topic, a better and a poorer class of patients had been spoken of. He did not think it was the experience of any present that the "better class," whether so distinguished because of education, wealth, or social recognition, were less given to animal indulgence than the poorer class. The paper further suffered in that the author had failed to define the meaning of "better class." He had stated that these people lied for self-protection; but, to carry such an argument to its legitimate conclusion, theft, gambling, and almost any crime could be excused on the same ground.

It was true that physicians of experience had very generally called attention to the fact that the opium habitué was a liar; but the reason for his being so was not that he was an opium habitué, but because his *morale* suffered under the influence of the drug, as it did under the influence of chloral, hashish, etc. Dr. Spitzka said that in the great majority of cases the opium habit was contracted through a selfish purpose or vicious tendency, and long after medical indications for its use had ceased to operate. Nine out of ten persons who applied for admission to homes for opium habitués were those who had become acquainted with the drug as doctors, nurses, or attendants in hospitals, not through taking it for long suffering. But the claim had not been made by any scientific authority that the opium habitué was always an habitual liar. Regarding another point touched upon, he might say that in his opinion not more than five out of a thousand persons who had habitually used opium for more than six months could ever free themselves from the trammels of the drug. It was certainly the most fascinating narcotic which had ever been presented to the human species. One of its principal dangers was that the system could become adapted to it. The drug was capable of influencing the descendants of its habitués to an almost incredible degree. Children born of mothers who used morphine became affected soon after birth with delirium and symptoms manifested by those deprived of their accustomed large quantity of alcoholic spirits, and, unless they received morphine, they would die. He thought the paper would have rendered a far better service had it directed attention to the disgusting and demoralizing aspect of the question, instead of placating the vice.

Dr. Wood said that according to his observation persons who were opium habitués were liars with regard to their habit as long as they continued it, but when they entered an institution for treatment, or had become cured, they became as truthful as other people. He thought the habit was not increasing in this country in proportion to the increase in population.

Dr. Nathan Brill endorsed what Dr. Spitzka had said, and added that opium habitués first lied about their habit, and, as their friends tried to reform them, they soon began to look upon them as enemies, and lied about other things. No other drug had as great an influence on the moral sense, and this influence he believed was transmitted from generation to generation.

William A. Purrington, Esq., read a paper on

The Desirable and the Practicable in Legislation Regulating the Practice of Physic and Surgery.

There were persons, he said, who believed the world was governed too much; there were others who would legislate to regulate the fee and the dose of medicine in every case. In considering the practical in medical legislation, it should be remembered that no law could be efficiently administered to which the people generally were opposed. In fact, public need and demand were always in advance of an enforceable law. What is particularly necessary in a medical law is that it should strike the community, especially those entrusted with its enforcement, as being fair. The law should not attempt to decide what is regular and what is irregular medical practice. It should only make general rules, establish certain requirements, and not decide that one sect and not another had a right to practice. But it had been pretty well established that an educational qualification was universally desirable and therefore practicable in any medical law. Such a qualification would not prevent one from practicing homœopathy or other method, although it might result in there being fewer homœopaths. It is desirable to have the examining board independent of the teaching board. All medical legislation should be in the interest of the people, and not class legislation favoring the doctors.

Mr. Purrington, it may be stated, is the very able counselor of the Medical Society of the County of New York.

SPECIAL CORRESPONDENCE.

MEDICAL JOTTINGS FROM THE OCCIDENT.

SAN FRANCISCO, CAL., May 25, 1888.

I have just returned from a trip over the "Sierras" into Nevada, among the Humbolt Mountains—500 miles from San Francisco—to see a patient. This is a country of magnificent distances; counties as big as States; States as large as empires. In truth, visits of five miles in the East have been attended with more discomfort to me than this run over into our sister State. It is surprising the distances doctors often make in visiting in the sparsely-settled West. From Rye Patch, Nevada—where I visited—it is usual to send to Reno, over one hundred miles away, for a physician. In some parts of the mining-districts, a doctor is engaged to live among the miners, each paying a dollar a month toward his maintenance—the income averaging $1,200 a year.

The climate now and through the summer, on the plateau of Nevada, is bracing and delightful. A tired-out doctor or a nerve-worn patient would find Reno, at the base of the Sierras, or Truckee, on the slope, or Lake Tahoe, most pleasant and healthful.

We certainly can claim a glorious climate on the Pacific Slope; but some people, among whom are certain physicians, have an exalted opinion of its curative value.

On my way home from Nevada, there was a lad of eighteen years, in the very last stages of consumption, aboard the train, *en route* for California, sent out, as he says, by friends and *his doctor*. Now, this is crowding climate a little too hard. It was a sickening sight to see the utter helplessness of this poor boy, depending upon the sympathy of travelers for his every want and movement—filled with false hope—deluded into the belief that California is the consumptive's paradise—once here, all would be well. What a pity he cannot die among friends and relatives. He will swell our already heavy death-rate from phthisis pulmonalis; for it is a fact that the death-rate from lung-diseases stands at the highest in San Francisco. It is true, many of the cases are imported; nevertheless, it is a proof that the climate did not heal. Each county in this State, through the circulars of the Board of Trade, goes into particulars of the peculiar virtue of its especial climate. The entire subject of climate in California, however, can be made very simple. The daily *Call*, in commenting on

"California as a Sanitarium,"

Quotes Dr. J. W. Robertson, Assistant Physician of the Napa Asylum, as saying: "In this State there are three distinct belts of climate, with wholly different therapeutic influences. Invalids who would derive benefit from one of the three might be unfavorably affected by the two others." Dr. Robertson classifies them as coast, valley, and mountain, and explains the qualities of each:

"The coast-belt extends over eight degrees of latitude, but is only from ten to twenty miles wide. In it, snow is phenomenal and frost rare, and, owing to the Japan current, it enjoys a temperature more uniform throughout the year than that of any other part of the world of equal size. Winter is warm and summer is cool, and the fresh salt air from the sea acts like a tonic on the system. It goes without saying that such a climate must be beneficial to a large class of invalids. But it is not without its drawbacks. The fierce heat of the Sacramento and San Joaquin valleys rarefies the atmosphere and causes a constant rush of sea-air through the Golden Gate to fill the vacuum; hence, for several months in summer, clouds of sand and dust sweep through the streets of San Francisco, and all along the coast-line damp fogs roll in, which chill the invalid to the marrow. These conditions indicate the class of invalids who are likely to benefit by a residence on the coast. Such are especially persons suffering with malaria in any form. Malaria does not originate here, and, when brought here, it usually succumbs to the climate, without medicine. It has also been noticed that patients attacked with kidney-troubles, or suffering with visceral lesions resulting more or less indirectly from malaria, derive benefit from a residence on the coast. Along the whole coast, except in large cities, endemic and epidemic diseases are unknown; and, if there is any merit in the theory that the searching west winds blowing in from the sea act as a germicide, all diseases of bacillary origin should be checked by a residence on this coast. On the other hand, there is no doubt that the coast-climate is injurious to invalids suffering with rheumatic troubles. These seem to be aggravated by the harsh winds and the raw fogs. It has also been noticed that the coast-climate affects unfavorably patients suffering with biliary diseases.

"The therapeutic quality of the two other belts is more easily determined. The

mountain-belt can safely be recommended in almost all diseases; its pure air, its bracing winds, its cool temperature, and, if used discreetly, its mineral waters, are almost always beneficial. The valley-belt has the disadvantage of combining excessive heat, and, in certain locations, malaria, and not infrequently diphtheria and other endemic diseases; the judicious searcher for health will select, if he prefers that belt, locations sufficiently elevated to be beyond the reach of miasma, and free from the exhausting heat of the plains."

In commenting on California as a sanitarium for consumptives, Dr. Robertson pointedly observes that, if consumption proceeds from the presence of a disease-germ, a germicide, and not a climate, is essential for a cure. Still, there is no doubt that consumptives in the incipient stage do derive benefit from a residence in parts of California. The place to choose is one of the health-resorts which have been established in the interior valleys, some two or three thousand feet above the sea, where outdoor exercise is possible in all weathers, and the air, naturally pure, is impregnated with the balsam of pine and fir trees. In such resorts, consumptives may recover perfect health, or, at any rate, may enjoy many more years of life than they would have had in any of the States of the East.

A peculiar effect of the climate in San Francisco is to twist about the medical courses. The announcement of the Cooper Medical College says:

"The regular course commences on the first Monday of June of each year, and continues until November. It is thus a summer course, contrary to general usage. In San Francisco, the disadvantages attendant upon such a plan do not exist. The heat is never oppressive or enervating; on the contrary, the sea-winds are bracing and invigorating. There are no rains during the lecture-months; the atmosphere is dry, and temperature rarely above 70°, while it ranges considerably lower. These circumstances tend to prevent decomposition, and add many advantages to the prosecution of dissection."

This same plan holds true of the medical department of the University of California. Both of these schools demand a three years' course.

There is also a Hahnemann Medical College in this city; but, from all I can learn, it cuts a very small figure. In fact, homœopathy does not seem to be in a vigorous condition here. It is customary in the East to speak of the great popularity of this "*ism*" in the West. I am quite sure that the cream of the practice in San Francisco is in the hands of the regulars, *and, after them, of the traveling quacks.*

The town has just been visited by a graduate of the Women's Medical College of Pennsylvania—a lecturing-tour, with visits at the hotel; and, I understand, she claims in a few weeks to have carried $20,000 away.

Yours truly,

C. C. Vanderbeck, M.D.

Periscope.

Case of Charcot's Disease.

At the meeting of the Medical Society of London, March 26, 1888, Dr. C. E. Beevor showed a patient fifty-three years old, a carpenter, who was suffering from locomotor ataxia with disease of the left shoulder-joint. There was no history of syphilis. Two years ago, he suffered from weakness and giddiness, with shooting pains in the legs and then in the arms; for eighteen months he had been subject to frequent flatulence and eructations; for one year he had difficulty in walking in the dark; and for the last four days he had œdema of the left arm. At present he had only slight staggering with the eyes shut and was unable to walk "toe and heel" along a straight line; he had slight lightning pains in the legs, and especially in the arms, and sometimes also in the head. The pupils were small; they reacted to accommodation, but not to light; the knee-jerks were absent, and there was no anæsthesia of the legs. Eight weeks before (January 30), the patient noticed that the left shoulder began to swell, but without pain; he never had suffered any injury in it. At the time of the report (March 26), the joint was much enlarged, distended with fluid, and grating could be obtained; the head of the humerus could be felt with difficulty, but it did not seem to be wasted. The disease probably involved especially the upper part of the cord, as shown by the lightning pains in the arms and head, the slight amount of staggering with the eyes shut, the absence of anæsthesia in the legs, and the affection of the shoulder-joint. He had no attacks of vomiting, but suffered from frequent flatulence.—*Lancet*, March 31, 1888.

Spontaneous Evolution of Face Presentation into Vertex Presentation.

Frömel reports in the *Wiener med. Presse*, February 12, 1888, the following case from

the obstetrical wards of Prof. Breisky. A multipara, whose previous labors had been normal, presented, when admitted to the hospital, the following points of clinical interest: Examination of the pelvis showed a slight contraction of the external diagonal conjugate; the promontory of the sacrum was readily reached; the uterus was deflected to the mother's right side; the back of the child was on the mother's left side, the face presented, the forehead being on the left side and the chin directly opposite upon the right; the head was high in the pelvis and freely movable.

The patient was ordered to lie on her left side, to rectify the position of the uterus. Three hours after the first examination, the membranes ruptured spontaneously, and the vertex presented, in first position, with the right arm. While efforts were being made to replace the arm, delivery occurred spontaneously. Frömel thinks that the following predisposing causes of face presentation were present in this case: The patient was a multipara; the uterus was deviated from its normal position toward the mother's right side; the head was large, and, while the membranes were intact, it remained obliquely at the superior strait, its posterior circumference resting against the left ilium; the occiput thus encountered greater resistance than the forehead, which descended first; prolapse of the arm was present; the head was large, but not dolichocephalic; the liquor amnii was abundant. The evolution of the face into the vertex presentation was effected by the contraction of the distended uterine muscle upon its left side, and favored by the position which the patient assumed, lying on her left side.—*American Journal of the Med. Sciences*, April, 1888.

Influence of Turpentine upon the Blood and Nutrition.

At the meeting of the Therapeutical Society of Paris, April 11, 1888, M. Brémond made a communication upon the influence of the turpentine treatment upon the richness of the blood in oxyhæmoglobin and upon the activity of reduction of this oxyhæmoglobin. He reported observations made upon three phthisical patients, who had undergone the turpentine treatment. The blood was examined by M. Hénocque in two of these patients, and the clinical results of the treatment were controlled by Dr. Fernet. The quantity of oxyhæmoglobin, its activity of reduction, and the weight of the patients were carefully noted during the continuance of the treatment. Microscopic examination of the sputa showed a marked diminution, and even a disappearance, of the bacilli which were present at the beginning. The increase of oxyhæmoglobin in these three observations confirms the opinion of M. Brémond as to the good effects upon nutrition of the turpentine treatment. These good effects are the result of more exact oxidation, due to a transformation of the oxygen of the blood into ozone by the turpentine which has penetrated into the torrent of the circulation. —*Gazette Hebdomadaire*, April 27, 1888.

Overwork of the Heart in Apprentices.

At the meeting of the Society of Public Medicine and Professional Hygiene, March 28, 1888, M. Layet, of Bordeaux, stated that he had had several recoveries from purely functional cardiac troubles occurring in young workmen of fourteen or seventeen years of age. They occur nearly always, he says, as the sequel of fatigue caused by work, without this work having been beyond the strength of the young men. It ceases upon rest, and reappears when the work is resumed and continued.

M. Layet explains this affection by saying that at the period of puberty the heart grows especially in volume, and this is the more rapid according as the period of the establishment of puberty is itself more rapid. Moreover, at this time the organism is in a condition in which it is less able to resist fatigue. It therefore follows that any work tending to increase the functional movement of the heart during this period can but favor the physiological tendency of this organ to dilate, and dilate at the expense of its contractile power, hence the signs of a nervous exhaustion, and not those arising from organic wear and tear.—*Bulletin Médical*, April 22, 1888.

Spontaneous Hemorrhage from a Normal Conjunctiva.

Perlia reports to the *Münchener Med. Wochenschrift*, No. 8, 1888, the case of a domestic, seventeen years old, who was subject to bleeding from the left conjunctiva; this occurred since she was two years old, upon severe bodily exertion, especially in a stooping posture. Violent beating of the heart and dizziness preceded it, and there was dysmenorrhœa. During the bleeding the color of the face was cyanotic, and the venous plexus of the conjunctiva was strongly

injected. The blood flowed from a large vein over the little lachrymal sac close to the middle palpebral ligament. By correcting the condition of the body, the bleeding ceased after some time. Perlia, in the absence of any local cause to account for the hemorrhage, believes that it must be referred to the dysmenorrhœa, as both happened at the same time at the beginning of puberty, and also, as is well known, congestions about the head are frequently connected with anomalies of menstruation.—*Centralblatt für die med. Wissenschaften*, May 12, 1888.

Nodular Rheumatism and Muscular Atrophy.

It has been asserted by Charcot, says the *Lancet*, June 2, 1888, that there exists no necessary relation between the intensity of the articular disease and the atrophic changes in the muscles. Parizot, basing his conclusions on a large number of facts, admits that a simple hydrarthrosis, neither inflammatory nor painful, may be followed by muscular atrophy in all respects like that which accompanies the most intense forms of arthritis. In these cases the rule is to find no reaction of degeneration, but marked exaggeration of the reflexes, indicating an excessive excitability of the spinal cord. These facts were well attested and confirmed by the paper communicated to the Royal Medical and Chirurgical Society by Dr. Archibald Garrod. Ollier and Mondan believed that functional inertia, as well as nutritive derangements in the epiphyses, accounted for the amyotrophy. But Sir James Paget long ago showed that mere disuse was insufficient to account for the atrophy resulting from surgical diseases of bone. Mayet and Cuilleret believe that there are nervous lesions to account for the amyotrophy.

Cancer of the Stomach in a Girl Seventeen Years Old.

H Köster, in reporting this case in the *Upsala Lakäre förenings Förhandlingar*, Bd. XXIII, Heft 4 und 5, remarks that the case deserves notice for the interest which it has as bearing upon modern operations on the stomach, and also for the rarity of cancer in a person so young. The patient, whose father had suffered from disease of the stomach, but who was otherwise free from hereditary taint, was taken sick early in 1887, with vomiting of blood, which, however, never had the well-known coffee-ground appearance. Associated with the vomiting, which recurred at irregular intervals, were emaciation, and shortly before her admission to the hospital, May 8, an eruption of petechiæ scattered over her whole body. The stomach was decidedly dilated, and at times a tumor could be felt in the epigastrium; there was no tenderness or pain accompanying it. The gastric juice contained no free hydrochloric acid. There was some thickening in the right upper lobe of the lung, but the sputa contained no bacilli. Death occurred in the latter part of June, the patient then weighing 13.5 kilograms. At the autopsy, besides numerous nodules of cancer scattered over the peritoneum, there was found an ulcerating scirrhus of the pylorus, the canal of the latter being extremely narrowed. There were no other metastatic growths. In the right upper and middle lobes of the lung was found a decomposing thrombus.—*Centralblatt für Chirurgie*, May 19, 1888.

Pernicious Eclampsia.

At a recent meeting of the Imperial Royal Medical Society of Vienna, Professor Gustavus Braun reported a remarkable case which he had the opportunity of observing at his clinic, during the month of March of the current year. A woman, twenty-eight years old, who had already been confined twice, and frequently suffered from peculiar spasmodic attacks, was, on March 17, admitted into his clinic in an unconscious condition. She was then in the seventh month of pregnancy, and suffered with typical eclamptic attacks. The patient was exceedingly pale, with slow respiration; pulse, 68; she foamed at the mouth, and had bitten her nether lip. There was much albumin in the urine, and a few casts. As labor had already begun, and the cardiac sounds of the child could not be heard any longer, rapid delivery of the woman by operation was determined upon. The child was extracted, the placenta artificially displaced, and artificial respiration practiced upon the patient. Death, nevertheless, occurred, owing to pulmonary œdema. Dr. Paltauf reported on the results of the post-mortem examination of this interesting case. A great quantity of liquid blood was found in the abdominal cavity; the hepatic capsule was detached by a layer of blood. The liver was enlarged throughout; the hepatic tissue was yellow, and pervaded by small blood extravasations. Interstitial nephritis, cerebral œdema, and general

anæmia were, moreover, present. The blood was unusually liquid. Dr. Paltauf mentioned some similar recent observations, and quoted the publications of Virchow, of the years 1881 and 1882, on cases of poisoning with sea-mussels, in which similar changes of the liver as in the case above mentioned were found to be present. Dr. Braun excluded poisoning with phosphorus and the presence of pathogenic bacteria, and arrived at the conclusion that they had to deal with a peculiar case of pernicious eclampsia, which was probably due to poisoning. In such cases the chemical poison entered the intestine and the liver; it afterward gave origin to a capillary phlebitis, stasis, blood extravasations, and even to partial necrosis of the tissue. As nephritis was present in all these cases, an elimination of the poison could not take place, and rapid death, for this reason, invariably occurred. The detachment of the hepatic capsule and the hemorrhage into the abdominal cavity were to be explained by the changes of the liver and the results of the artificial respiration.—*Medical Press and Circular*, May 16, 1888.

Peculiar Form of Keratitis Occurring in Intermittent Fever.

Van Millingen describes in the *Centralblatt für Augenheilkunde* a peculiar form of inflammation of the cornea which occurs in intermittent fever. This manifests itself in the form of a superficial erosion at the temporal border or more rarely at some other peripheral part of the cornea; and this erosion is occasioned by loss of epithelium in a spot of irregular outline. The area so deprived of its epithelium is at first clear, but soon becomes cloudy and shows irregularities. By destruction of the epithelium at the border of the ulcer, the latter enlarges until it reaches or even passes beyond the pupillary area. Soon after complete destruction of the epithelium, deep infiltration occurs in the affected area. The ulcers which occur in the second stage of the disease have no disposition to perforate the cornea. Around the infiltrated spots are formed streaky, radiating, or stellate prolongations, which extend into the clear portions of the cornea. The iris and choroid take no share in the inflammation. The symptoms are different, according to the stage of the disease: in the beginning, there is local pain and a feeling as of a foreign body in the eye, together with lachrymation and dread of light; in the second stage, there is ciliary neuralgia. The symptoms, however, in neither stage are constant, and even pain may be absent. A constant and very important symptom is anæsthesia of the cornea, which may even extend to unaffected parts of the latter, and which sometimes persists a long time after complete healing has occurred. The whole process is a sluggish one, the ulcer having a tendency to enlarge rapidly. A disposition to reparation is slow in making its appearance. The first indication of it is vascularization at the border. The result of the disease is very serious, as regards the function of the affected eye. A dense opacity of the central part of the cornea is a frequent result. Recovery occurs through cicatrization. Frequently large facets are left upon the cornea. The clear areas are beset with stellate opacities, so that there is little prospect of a successful result from an iridectomy. In all cases the connection of the affection with intermittent fever was proved, and recovery from the fever secured through the use of quinine, which also checked the progress of the eye-disease.—*Wiener med. Presse*, May 13, 1888.

Peculiar Syphilitic Affection of the Conjunctiva.

At the meeting of the Verein Deutscher Aerzte in Prag, March 16, 1888, Prof. Sattler stated that syphilis of the conjunctiva is extremely rare, as, among the many thousand patients seen by him, this affection had come under his notice but once. From the small number of trustworthy observations of this disease which have been made, it is learned that the affection occurs as the chancre, the papular syphilide, and the true gumma. In connection with the two cases of syphilitic conjunctivitis very recently communicated by Goldzieher, and with an older case of Macauley's, Sattler reported a singular observation which he had had the opportunity of making while he was assistant at the clinic of Arlt in 1873.

The patient was an anæmic woman, forty years old, whose pale but otherwise little-changed conjunctiva was occupied with a large number of granules of different sizes, which were seated in the conjunctival folds of both eyes. The affection was regarded as trachoma, and treated as such, but without success. When the patient subsequently came to the clinic, she presented pronounced symptoms of constitutional syphilis. Energetic antisyphilitic treatment caused the complete disappearance of the conjunctival affection. This cleared up the nature of

the disease, and, besides, a piece of tissue examined under the microscope showed a very different appearance from that seen in trachoma. The granula exhibited peculiar growths of endothelial elements.—*Wiener med. Presse,* May 6, 1888.

Mode of Action of Cocaine.

At the meeting of the Biological Society of Paris, May 5, 1888, M. Ch. Richet stated that he had been making some experiments to determine how the epileptic convulsions, which follow the administration of large doses of cocaine, are produced. He first found that the dose necessary to produce convulsions in the normal state was in the ratio of one-third of a grain to each kilogram of body-weight of the animal. Having cut the spinal cord before giving the drug, and found that the convulsions did not occur, it was clear that they were not caused by any action upon the cord. To determine upon what part of the brain it acts, he removed a large part of the motor zone. He then found that, while the convulsions were still produced, they changed their form, becoming more clonic, and that the dose of cocaine necessary to produce them was considerably larger—one-half to four-sixths of a grain for each kilogram. The conclusion from these researches is that cocaine provokes convulsions by its action upon the whole mass of the brain, but its predominating influence is probably exerted upon the motor nerve-cells of the cortex.—*Bulletin Médical,* May 13, 1888.

Trephining for Paralysis.

At the meeting of the Medico-Chirurgical Society of Edinburgh, February 15, 1888, Dr. Felkin showed a patient of his who had been trephined by Mr. Hare, over the motor areas of the brain, for localized paralysis. There was commencing return of the lost functions. The patient was a girl, 17 years old, who had received a fracture of the skull when ten months old. The right arm and leg were almost completely paralyzed; they were shorter than the left arm and leg, and badly developed. The temperature was 2° lower than on the left side; the reflexes were exaggerated, and sense of locality and tactile sensation were absent. At the operation, which was performed a month before, a large cyst, which extended to a depth of two inches from the surface of the skull, was found, and also an osteophytic growth, which extended inward half an inch toward the surface of the brain. The patient made a good recovery. She walks better, can move her arm to a considerable extent, and both reflexes and temperature now correspond on both sides of the body. The case will be published in full at some future date. —*Edinburgh Med. Journal,* May, 1888.

Rupture of Vermiform Appendix; Laparotomy; Recovery.

Dr. Brenner, assistant to Professor Von Dittel, recently showed a patient before the Imperial Royal Society of Physicians, at Vienna. He was nineteen years old, and had been admitted into Professor Von Dittel's clinic in March last, with symptoms of severe intestinal obstruction. The history of the case and the intense pain in the cæcal region led them to conclude, with a certain degree of probability, that they had to deal with perityphlitis and consecutive suppurating peritonitis. Laparotomy was performed on the day of admission. After opening the abdomen, a great quantity of pus escaped; the intestines were washed with a solution of salicylic acid; and, on close examination, it was found that there was an abscess in the region of the cæcum, around the vermiform appendix, which was perforated. The vermiform appendix was ligatured and removed. The part of the cæcum which had become affected by the suppurating process was drawn forward and fixed to the abdominal wound by means of sutures, as resection of the intestine could not be done, owing to the collapsed state of the patient during the operation. The abdominal wound was closed, and healing took place by first intention. Three other cases of suppurating peritonitis following perityphlitis were treated in the wards of Professor Von Dittel by laparotomy, but all ended fatally. Dr. Brenner remarked that the recent advance in the surgical treatment of these cases consisted in the fact that operation was resorted to at an early date, and that the affected part of the intestine was removed from the abdominal cavity. This was the first case of healing after resection of the vermiform appendix, when general peritonitis was already present.—*British Medical Journal.*

—A hospital for the treatment of diseases of the throat, nose, and lungs is to be built in Brooklyn.

—The British Medical Association will hold its fifth annual meeting at Glasgow, beginning August 7.

New Theory as to the Origin of Ulcer of the Stomach.

In the *Nordiskt med. Arkiv*, Bd. xix, A. F. Rasmussen states that at autopsies he has usually found a furrow upon the stomach, which he is disposed to attribute to pressure from without and to compare with the furrow from lacing, which is found upon the liver. In some cases he has seen such a furrow extend from the liver across the stomach and upon the descending colon. Along the indented part of the stomach Rasmussen found the serous coat thickened, while the mucosa was atrophied. He offers the hypothesis that pressure upon the stomach in all or at least many cases is the cause of the formation of ulcer. He bases this hypothesis upon the observation that symmetrical scars following ulcer of the stomach are often seen upon the anterior and posterior walls of the stomach, and that they have their seat for the most part in the smaller curvature, and more frequently on the posterior than the anterior wall—places which are especially exposed to pressure, while the greater curvature is more movable.—*Deutsche med. Wochenschrift*, May 17, 1888.

Myositis Ossificans.

Dr. A. A. Lendon, of Adelaide, has recorded in the Transactions of the First Intercolonial Medical Congress (August and September, 1887) the particulars of a remarkable example of the very rare disease, myositis ossificans. The paper is the more valuable since it comprises full anatomical details, with illustrations of the skeleton of the subject. The man died at the age of forty-six, having first shown signs of the affection when only eight years old; but he had always been clumsy with his right arm and forearm, and as during boyhood the stiffness increased, it was attributed to injuries received at various times. He became greatly deformed, with bent rigid back and limbs, and before his death he suffered from numerous bed-sores, and was reduced to a pitiable state. Many muscles were partially or wholly converted into bone, notably both latissimi, which caused the scapulæ to be firmly fixed to the thoracic cage. In the limbs the joint surfaces were fairly normal, or the cartilages in fibroid degeneration, although the joints were greatly surrounded by irregular masses of bone due to ossification of muscles and ligaments. The spinal and costal ligaments were all ossified, making the back quite rigid. Dr. Lendon also quotes an interesting description of a similar case from a work on the city of Cork, by Charles Smith, published in 1750, and reproduces the engravings that represent the skeleton of this case. Reference is made to Mr. Sympson's paper on the subject, to the case described by Mr. Cæsar Hawkins, to the specimen in the Hunterian Museum, and to some recently-recorded cases, which, however, lack the post-mortem evidence which renders Dr. Lendon's essay so important to the pathologist.—*Lancet*, April 21, 1888.

Epidemic of Sore Throat in Edinburgh and its Relation to the Milk-Supply.

At the meeting of the Edinburgh Medico-Chirurgical Society, June 6, Dr. G. Sims Woodhead and Mr. J. M. Cotterill read a paper of much interest on a curiously limited epidemic of sore throat, and suggested a relationship with the milk-supply. Mr. Cotterill was called to attend successively a large number of cases of sore throat occurring in an educational institution in the city. The grouping of the cases raised the suspicion of infection from a common source, and, after careful exclusion, Mr. Cotterill came to the conclusion that the mischievous factor was to be found in the milk-supply. This was accordingly suspended, when the sore-throat epidemic quickly disappeared. When the milk was recommenced, sore throats of a similar character appeared again. Then all the milk was boiled before use, when the epidemic similarly yielded. Dr. Woodhead's attention was accordingly called, and he instituted a careful examination into the condition of the cows from which the milk-supply in question was obtained. Most of the animals showed unmistakable signs of cow-pox in the scab stage. One cow, which had been separated from the rest as specially healthy, and whose milk was devoted to the use of a hand-fed child, showed similar appearances. On inquiry, it was discovered that the child too, as well as other persons who had partaken of the special milk, suffered likewise from sore throat of similar character. The clinical evidence thus appeared strongly to support the view that the milk was the medium of infection from the diseased animals. Dr. Woodhead then undertook a series of cultivations and inoculation experiments. He examined the matter from the teats of three of the diseased cows, and found streptococcus pyogenes in all; further a very small bacillus in the discharge from two,

and several other organisms in that from one. In the matter from the tonsils he discovered the streptococcus pyogenes, the slender bacillus, and a very small micrococcus. In two instances there was found, in addition, the short thick bacillus. By cultivation from these and from the milk, no less than fourteen distinct organisms were separated. Of these four were common to the milk, to the discharge from the sores, and to the tonsils, while seven were found common to the milk and the sores. It is possible that some of the others may be found common to the three sources, but so far they have not yet been obtained pure. Inoculation experiments were conducted on rabbits with the several pure cultivations whose derivation has been detailed. The results so far obtained have been entirely negative, the staphylococcus pyogenes amongst others not producing any effect, except a very slight amount of swelling and transient redness at the seat of inoculation. Inoculation was made by means of subcutaneous injection into the rabbit's ear.—*British Med. Journal*, June 9, 1888.

The Eye in Chorea of Childhood.

Dr. G. E. De Schweinitz, in a communication to the *New York Medical Journal*, June 23, 1888, based on an examination of fifty cases of chorea of childhood, gives the following conclusions, which he thinks are justifiable:

1. The irides of choreic children quite commonly present chromatic asymmetry in shade, just as the same condition has been found in other forms of nervous disorders. 2. Slight differences in the width of the pupils may be observed, but not more frequently—in fact, not as frequently—as these have been noted in perfectly healthy individuals. 3. Facial asymmetry is present in about one-half of the cases, just as this is present in cases of high refractive error, and also in individuals perfectly free from nervous disorders. 4. Hypermetropia and hypermetropic astigmatism are vastly the preponderating conditions of refraction in the eyes of choreic children, being found in about 77 per cent. of the cases, exactly as hypermetropic refraction is the preponderating condition in childhood generally, being found in 76 per cent. of the eyes of children in the elementary school years. 5. Imperfect equipoise of the eye-muscles is found in the great majority of the cases, but imperfect equipoise of the eye-muscles is very frequently present in the eyes of schoolchildren free from chorea or neuropathic tendencies. 6. Embolism, atrophy of the disc, and optic neuritis may occur during or after attacks of chorea, but appearances in the fundus oculi characteristic of the disease have not been found. 7. As Octavius Sturges remarks: "It seems certain that a fairly constant proportion of chorea is directly connected with what may be called injudicious schooling, . . . but such nice adjustment as shall prevent overstrain on the one hand and overindulgence on the other is practically unattainable." Certainly an endeavor to lessen the overstrain of the eyes should be made; hence the refraction-errors and muscular defects in these children should be carefully and fully corrected by glasses, by prisms when necessary, or even by judicious surgical interference, and thus a probable exciting element removed; just as we should perform the same service for eyes similarly afflicted in children who are not choreic; just as we should improve the hygiene, remove the anæmia, treat the disabled circulatory apparatus in children who are choreic. Evidence, however, seems quite as lacking that hypermetropic refraction is the basal cause of chorea as it is that the chorea is the cause of the hypermetropia.

Remarkable Case of Narcolepsy.

Dr. Caton has recently had a remarkable case of narcolepsy in the Liverpool Royal Infirmary. The patient was a man thirty-seven years old. He would fall asleep while standing, when selling articles in his shop, or even when walking in the streets. If he attempted to read or to sit in a chair, he invariably fell asleep in a moment. During sleep, a spasmodic closure of the glottis always took place, lasting nearly a minute. Violent contraction of the diaphragm and other respiratory muscles would come on, increasing in force, and the patient would get more and more cyanosed, until at length the violence of the inspiratory efforts partially roused him, and the spasm of the glottis yielded. Loud noisy respirations would now come on, and the cyanosis would disappear, to be followed by deep sleep and the same round of symptoms. This condition has existed for six years, and the seizures continually occur by day and by night. When awake, the patient is perfectly intelligent, and there is no evidence of organic disease. The kidneys are healthy, and secrete abundance of urea. Dr. Caton supposes that the symptoms are due to the formation of some narcotic alkaloid in the alimentary canal or the blood, and this view

was strikingly confirmed by the results of treatment, most benefit being derived from a limitation of diet and the administration of charcoal and naphthaline three or four times daily. Under this treatment, the drowsiness diminished considerably, and the spasm of the glottis disappeared altogether; but, when the treatment was suspended for some time, the symptoms returned.—*British Medical Journal,* June 9, 1888.

Etiology of Aortic Aneurism.

Dr. Karl Malmstein, of Stockholm, has published notes of one hundred and one cases of aortic aneurism occurring in his own practice, or in that of other Swedish physicians, with the view of elucidating to some extent the causes of this affection. He remarks, however, that it is impossible to say how many persons die of aortic aneurism, for the condition is very frequently not diagnosticated, and the cause of death is returned as due to cardiac disease, hemorrhage, or other ill-defined cause. As to the seat or seats of the aneurisms in the cases collected, information could be obtained in only ninety-two instances. Of these, eighty-three were single, the arch being affected in fifty-seven, the descending aorta in seventeen, the abdominal aorta in four, and the arch and the descending aorta together in five. In eight cases there were two distinct aneurisms, and in one case three, two of them on different parts of the arch and one on the right coronary artery. These statistics fully bear out the observations of other physicians as to the greater liability to aneurism of the portions of the aorta nearest the heart. Dr. Malmstein also confirms the remarks of Stokes as to the want of connection between aneurism and cardiac hypertrophy. In about 80 per cent. of the cases, the existence of syphilis was definitely made out. There were but five cases in which gout or rheumatism existed, and in only five could alcoholism be assigned as a cause; besides, it is remarked that in the Swedish military hospitals, though alcoholism is yearly decreasing, the number of cases of aortic aneurism show an upward tendency. The cases of aortitis chronica petrificans, or senile degenerative change, were few in number, and there was only one instance of a traumatic nature. Several beautifully executed engravings, illustrating syphilitic lesions classed by the author as aortitis sclerogummosa, are appended to the work.—*Lancet,* May 26, 1888.

Etiology of Purulent Bronchitis.

Professor S. V. Levashoff describes in the *Ejenedêlnaya Klin. Gazeta* an interesting case of purulent bronchitis occurring in a medical man, which may help to throw some light on the etiology of this disease. The patient was a man fifty-three years old, who had always enjoyed good general health, and had had no diseases of the respiratory organs, but had suffered occasionally from attacks of quinsy. In October last, after having been on a long journey in Siberia, he began to suffer with rigors at night and sweats in the morning. Some days later, cough came on, and he noticed a very foul smell in his mouth; he also began to expectorate a quantity of dirty gray mucus, which had the same foul odor, the sputum at times containing small lumps looking like bits of half-burnt rag. When he came under Professor Levashoff's care, he was evidently suffering with purulent bronchitis, the chief seat of the affection being in the left lung. Professor Levashoff took the utmost pains to find a means of accounting for the invasion of the disease, and at last came to the conclusion that something must have been introduced into the lungs from the outside which had caused the purulent secretion. On questioning the patient, he found that, when traveling in Siberia, in order to protect himself from the severity of the weather, he had covered himself with furs, felt mats, and other articles which are capable of conveying septic material, and it was doubtless in this way that the purulent bronchitis was brought on. The treatment adopted consisted chiefly of turpentine and carbolic acid inhalations, terpine, quinine, and narcotics internally, and energetic frictions with turpentine and lard over the chest. The disease presented a regular series of rises of temperature, with every third day copious discharges of purulent sputum, sometimes mixed with large quantities of blood. Notwithstanding all these very grave symptoms, complete recovery took place.—*Lancet,* June 9, 1888.

His Diagnosis.—"Got a cold, Hyson?" inquired Mr. Orrico Root of young Hyson, the other day. "Tell you what will stop it in five minutes—" But Hyson interrupted him. "I had a cold," he said, "the beginning of the week. What I've got now is a five-minute cure that a fellow gave me on Monday. Looks like a cold, though, don't it?"—*Puck.*

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.25**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

ELECTION OF A WOMAN TO THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

On Wednesday, June 20, the Philadelphia County Medical Society elected Mary Willits, M.D., to active membership. This marks an epoch in medical affairs in Philadelphia. For years the friends of women physicians have endeavored to bring about the election of women to the Society. Over and over again the names of reputable and estimable women have been proposed, reported favorably by the Censors, and then been rejected by the Society. Conservatism was so strong that some of the best representatives of the best medical college for women in the world were repeatedly refused admission to the society of the county in which it is located. Unwearied patience and unremitting perseverance have, however, at length led to the usual result, and the Philadelphia County Society has broken down the barrier which so long separated it in this respect from the practice of other influential medical societies.

The occasion is one for congratulation to those who believe that women physicians should not be debarred, on account of their sex alone, from membership in societies which are intended to include all reputable physicians and which are parts of the American Medical Association. There are medical societies so constituted that they may, with entire propriety, decline to admit to membership any candidate for any reason which seems to them good. But, in our opinion, the County Medical Societies are not of this number, and should admit all candidates whose standing as physicians and as individuals is good, except for reasons which would be recognized as sufficient by the mass of the profession.

For years the Philadelphia County Society has held a different opinion, and has refused to abandon it under very strong pressure. But at last, the most conservative society in the country has changed its mind.

This is a conclusion the importance of which is enhanced by the deliberation with which it has been reached. The election of a woman here and now means much more than it could have meant if the result had been secured at the first effort; and those who have labored and waited for it have achieved a success which will be all the dearer for all it has cost them.

Those who have opposed this result have reasons which are entitled to great respect; but these reasons are out of harmony with the spirit of the age, and they must give place to the force of numbers. Happily, the result of the last test-vote has not given rise to indiscreet jubilation on the one hand, nor to feelings of resentment on the other. The keynote of the state of affairs has been struck by Dr. John B. Roberts, who in a letter to the Philadelphia *Ledger* makes this graceful acknowledgment: "In regard to the recent admission of a woman physician

to the Philadelphia County Medical Society, it is but justice to say that we owe her election largely to the forbearance, good-will, and great-heartedness of our friends, who have for so many years *successfully opposed* our efforts to gain recognition of women physicians in that body.''

Thus, then, we chronicle this interesting event, and express the hope that its results will justify the expectation of those who brought it about, and convince those who conscientiously opposed it that it was right and good.

INCONTINENCE OF FECES.

From all points of view, incontinence of feces is a more unfortunate condition than incontinence of urine, and when it is well marked the patient becomes such a continual source of annoyance both to himself and to his friends that life is a burden. In aggravated cases, he can never feel himself safe in leaving home, so that by degrees his health is impaired through lack of fresh air and exercise, while his mental habit becomes one of settled melancholy. In this distressing condition, he is apt to catch at any method of treatment which seems to offer a chance of cure, and is exceedingly fortunate if he falls into the hands of an honest and skillful surgeon.

Sometimes involuntary discharges of feces are the result of sudden nervous impressions; but there are some cases which admit of surgical treatment. In regard to these, Mr. Herbert William Allingham makes some very important suggestions in the *Medical Press and Circular*, May 23, 1888.

Before speaking of the treatment, Mr. Allingham devotes a few words to the causes of this affection. He first takes up the case in which, in an operation for fistula, too deep a cut has been made through both sphincters, and says of it that the wound may heal in such a manner as to leave a deep sulcus. The result of this is that the continuity of the sphincters is interrupted at one point and their edges are curled outward by the contraction of the scar. As this contraction increases, there is a loss of muscular power, a widening of the sulcus, and gradually a loss of the muscular sense in the part, so that the patient is no longer able to appreciate the contact of feces until it is too late to prevent their escape. On exploring the bowel, the anus will be found larger than is normal, and the muscles contracting continually from the patient's sense of a weakness in them; and at the same time the muscles are thin, weak, and narrow, instead of broad, firm, and powerful. In such a case, Mr. Allingham recommends that, when the fistula is cured and the wound well healed, the everted and separated ends of the muscles may be freed and the sulcus lessened in depth by cutting deeply across the old scar and allowing the wound to heal from the bottom.

In another case, instead of there being one deep sulcus, the sphincter may have been divided in two places, and thus a weak splicing have ensued. This generally occurs, he says, when the muscles have been divided obliquely, instead of at right angles to their fibres. In this case, a loss of tone may be observed, and a consequent incontinence of feces. The longer an operation is deferred in such a case, the greater will be the paralysis of the part. An examination reveals two cicatrices: one on each side of the bowel, or perhaps two on the same side. There is then the same loss of power and lack of consistence of the muscles as in the first case, with this difference, however, that there are two weak points in the circumference of contractility. In fact, the muscles have been divided up into small segments, and the sphincters, as a whole, have been proportionately weakened.

Mr. Allingham's treatment for this condition is to burn deeply into both sphincters in several places with a Pacquelin cautery, and also to cauterize the old scars deeply. The resulting cicatrix will, he says, usually contract sufficiently to give the patient control over the bowel; and, if it does not, the operation must be repeated.

Another condition which the author describes is one brought about through the decussation of the fibres of the vaginal and rectal sphincters in women, which leaves a weak point at their junction in the perineum. If the anal sphincter should be divided at this point, incontinence of feces may result. There may be little evidence of anything wrong externally, and the finger itself may discover nothing except that from the location of the scar the fistula must have been perineal, and in some cases the anus may be seen to be drawn too far backward. For this condition, Mr. Allingham says Lawson Tait's operation on the perineum may be done; but he advises that the flaps should be turned into the rectum and sutured together, thus narrowing the anus. He prefers, however, to burn the sphincters deeply in the manner just described in speaking of the treatment of the second condition. In other words, the treatment advised for the distressing weakness in the second and third conditions is, briefly, to burn the affected parts in such a way as to produce a deep cicatrix and to utilize its well-known tendency to contract, in order to overcome the relaxation of the parts, which is the immediate occasion of the incontinence.

The treatment is not new, but is so easily performed that it deserves to be borne in mind as a method which has brought relief to many miserable patients.

TREATMENT OF EXTRA-UTERINE PREGNANCY.

Since 1869, when Dr. J. G. Allen, of Philadelphia, succeeded in arresting an extra-uterine pregnancy by the use of the Faradic current, electricity has been about the only agent used in this country in treating that condition. But the Faradic and the galvanic currents have been employed with the dosage regulated by the sensations of the patient. But one fatal result—in a case under the care of Dr. Janvrin—has followed the use of electricity, and that could not be attributed to the treatment. In no case has serious disturbance been set up by the retained fœtus or membranes. The Faradic current has been most commonly employed, one pole being applied within the vagina or rectum, and the other over the inguinal region. Rockwell and others employ the interrupted galvanic current. Prior to 1887, American operators, almost as a unit, favored this method, till the end of the fourth month of pregnancy. Garrigues sets no limit. In a few cases of interstitial pregnancy, the ovum has passed into the uterine cavity, and abortion resulted, after the use of the electric current.

Electricity has secured but few adherents abroad. Influenced by the favorable results in abdominal surgery, by the fact that the great majority of cases are tubal, and by *post-mortem* demonstrations of the feasibility of exsection, J. Veit, Martin, Tait, and others have done abdominal section, and removed the tube and contents. Many of the operations were done after rupture of the cyst, and were made for the arrest of hemorrhage. The results have been most excellent—of Tait's thirty-five cases, but two have died. There can be no question but that abdominal section should be done for the arrest of hemorrhage where rupture has occurred—at this early period, it is usually best accomplished by exsection of the cyst—for, otherwise, death is almost inevitable. Foreign authorities in general recommend, in the early months, removal so soon as a diagnosis is made. Mr. Tait, in particular, urges against electrical treatment that it leaves a foreign body in the abdominal cavity to undergo suppuration; also, that while it kills the fœtus, the placenta will continue to grow. It need only be said that thus far neither of these possibilities has occurred. Within the past year, however, there has been a reaction in this country, against the use of electricity, and a number of surgeons have successfully removed extra-uterine cysts.

If the pregnancy passes the fourth month, it is almost certainly intraligamentous, abdominal, or ovarian, and will probably go to term, when false labor will occur, followed by the death of the fœtus. The question of treatment is by no means so definitely settled after the fourth month, as before that time. Of seventeen cases collected by Litzmann and Werth, in which abdominal section was done during the life of the fœtus, only two mothers were saved. All the infants were living, but nine lived only from one to fifty hours. Litzmann gives partial approval to operation during fœtal life. He would operate at the tenth month, if the child were strong and well-developed. Werth advises against operation till after the death of the fœtus. Gussemo advises operation at the eighth month. Bandl would operate about full term, before false labor begins. Martin and Breisky have removed the fœtal sac entire with living children. The table of Dr. Harris shows that, judging from the experience of the past, the operator has but one chance in nine of saving the life of the mother, and one in two of saving that of the child, when the operation is performed during fœtal life. While it is the opinion of the majority that operation should be postponed till after fœtal death, a growing minority favor the attempt to save both mother and child. The question of laparotomy or elytrotomy is likewise unsettled. Thomas favors incision from the vagina if the tumor is low down in the pelvis. Abdominal section is usually preferred. When the pregnancy is intraligamentous, the peritoneal cavity should not be opened. This operation would not be laparotomy. The placenta should not be removed unless the entire sac can be exsected, as is done by Martin and Breisky.

After the death of the fœtus, the treatment should be expectant. Litzmann and Werth have proved the danger of operation to be as great after the death of the fœtus as before, unless time is allowed for the placental circulation to cease. Litzmann places this time at five or six months after fœtal death, while Werth would operate in ten or twelve weeks. After the cessation of the placental circulation, the entire sac has been removed by Litzmann, Billroth, Thornton, and Schröder. Schröder has seen a smart hemorrhage from the placental site, nine weeks after fœtal death. Operation may be called for at any time by rupture of the sac, suppuration, or peritonitis. In a few cases, the fœtus has been changed into a lithopædion. Unless the entire sac can be removed, the placenta should be left. Operation should be conducted upon the lines of modern abdominal surgery.

When cases are seen after suppuration has occurred, and the fœtal parts are being discharged by the abdominal wall, vagina, bladder, or intestine, nature should be assisted by enlarging the openings and removing presenting fœtal tissue. Operation will sometimes be necessary where the natural openings are in the bladder or intestine. Local antisepsis should of course be employed.

IODOFORM IN HÆMOPTYSIS.

We wish to call the attention of our readers to the claim made by two French physicians, Chauvin and Jorisenne, that iodoform is an efficient and prompt remedy for hemorrhage from the lungs. Its action is not confined to a temporary stanching of the bleeding, but usually checks the tendency to the recurrence of it which is so common, and when this does take place it is not nearly so grave as the first hemorrhage. One of the advantages of the use of iodoform in hæmoptysis lies in the fact that it is active in very small doses. The average dose used by MM. Chauvin and Jorisenne was about three-quarters of a grain. It was given in pill form, made up with extract of gentian or of licorice, and from three to five doses were given daily. It is said that the patients treated in this way were delighted with the method, and

MM. Chauvin and Jorisenne speak of it in the most enthusiastic way.

Anyone who has had much experience in the treatment of hæmoptysis knows that it often ceases spontaneously, and that it is not always safe to conclude, when remedies have been used, that art has accomplished what nature so often does without assistance. But it is not to be supposed that the physicians who praise iodoform so highly are ignorant of this fact, or have failed to take it into consideration. So, it seems quite worth while that the use of iodoform should be given a fair trial, especially as this drug is often of great value in the treatment of the condition in which hæmoptysis most commonly occurs.

Book Reviews.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the Reporter.]

THE SURGICAL DISEASES OF THE GENITO-URINARY ORGANS, INCLUDING SYPHILIS. By E. L. Keyes, A.M., M.D., Professor of Genito-Urinary Surgery, Syphilography, and Dermatology in Bellevue Hospital Medical College, etc. 8vo, pp. xvi, 704. New York: D. Appleton & Co., 1888.

Dr. Keyes is well known as a teacher and practitioner in the department of surgery to which this book is devoted, and it bears the marks of his experience and study. At first sight, it seems almost sacrilegious that he should have swept from the title-page the name of Van Buren, which did so much to bring into favor the volume of which we are told this is a revision; but Dr. Keyes justifies his act by stating in his preface that he, and not the late Dr. Van Buren, wrote that book, except four chapters of it; so it is not sacrilege, but it is a pity, we think.

There are other points about this book which invite criticism, and chiefly of a sort which is in keeping with the change in its title and the claim to authorship of its predecessor. Its scientific qualities are very fair, and certainly far superior to its forerunner. It presents a view of almost every subject covered by its title. This view is usually terse and dogmatic; so much so that some things which deserve mention are omitted and some errors have crept in; but in the main it is a safe guide and may be commended to the notice of our readers.

MEDICAL PUBLICATIONS. HARVARD MEDICAL SCHOOL. 1887. 8vo.

This book contains ten papers by men connected with Harvard, which have already appeared in various medical journals. It is intended to show the character of the original work done by instructors in this school or under their personal supervision during last year. It does not include all the original work of these men, but presumably contains what the compiler, Dr. J. Collins Warren, thought the best. We have not space in which to catalogue these papers, but we may say they are all of a very high degree of merit. One of the most interesting is that of Dr. Harold C. Ernst, called "An Experimental Research on Rabies." It was originally read before the Academy of Surgery of Philadelphia, and contains an admirable account of his experiments with material derived from two rabbits inoculated by Pasteur or in his laboratory and used for inoculation upon other rabbits in the manner of Pasteur. The description of Dr. Ernst's experiences is given in a manner which might well be taken as a model by Pasteur, and leaves no room for doubt that the effect of the inoculations furnishes very strong evidence in favor of the theory that the material used is what is called "specific." That it is the very virus of rabies, or hydrophobia, we do not believe; but this is not the place in which to argue the case. We can, and do, heartily commend the temperate scientific tone of Dr. Ernst's argument, and believe that he would do good service to the cause of science if he would continue his investigations and report their results from time to time.

Complicated Case of Occlusion of the Vagina.

Another instance of the rare cases in which a woman in labor is found to have complete occlusion of the vagina has been recorded by Dr. W. Zinsstag, of the Basle Gynecological Clinic. The patient, a young primipara, being in labor, on being examined by her family doctor, was found to have an occluded vagina. He, thinking this arose from sterrosis, sent her to the clinic. When first examined there, the finger felt a narrow canal, at the end of which a sharp-edged circular fold separated it from a somewhat more extensive cavity; behind this latter cavity the fœtal head was felt through the thick septum. On inspection it was discovered that the canal was not the vagina, but a dilated urethra, and the sharp-edged fold the sphincter of the bladder; the cavity was the bladder, and the membrane separating the finger from the fœtal head the posterior vesical wall. From the orifice of the urethra to the fourchette there stretched a strong bluish membrane, across which several veins ran. No opening capable of admitting the finest probe could be found. A somewhat similar case of persistence of the sinus urogenitalis is described by C. von Braun in his text-book. Coition must have taken place through the urethra, and some opening in the hymen must have existed, permitting the escape of the menses, which had been normal, and also allowing of the introduction of the seminal fluid. This orifice must have become closed up during pregnancy. Incisions were made in the hymen and in the perineum, and the labor was satisfactorily concluded.—*Lancet*, May 12, 1888.

CORRESPONDENCE.

The University Fire.

To the Editor.

Sir: We wish to make some acknowledgment to the resident physicians of the University and Philadelphia Hospitals, to students, and others who so energetically aided us in saving preparations, books, and apparatus at the recent fire in Medical Hall, but scarcely know how to reach them except through the columns of the medical press.

Will you permit the use of so much of your columns as will enable the Medical Faculty to heartily thank these gentlemen for their services? Very truly yours,

James Tyson, M.D., Sec'y.

University of Pennsylvania,
Department of Medicine,
June 19, 1888.

Queer Remedies.

To the Editor.

Sir: We have a man here that styles himself Dr. I. T. Hazel, who recommends the following remedy for epilepsy:

Take the false tongue of a new-born calf, which he says grows under the real tongue during intra-uterine life; dry thoroughly and powder, and give from five to ten grains three times a day.

This prescription ought to go with the Chinese remedy for typhoid fever, which is as follows:

℞.—Two fresh tom-cat heads,
One fried snake-skin,
Three inches dried umbilical cord,
One gallon water.

Macerate three days and give a tablespoonful every four hours.

Yours truly, J. T. Smith, M.D.

Harrodsburg, Ind.,
June 13, 1888.

Quinine Rash.

To the Editor.

Sir: I send you an account of a case occurring in my practice, in which there was a very marked idiosyncrasy in regard to quinine. The patient was a young woman, eighteen years old, to whom I was called because she had a severe supra-orbital neuralgia. I prescribed quinine, to be given in five-grain doses every two hours until she had taken four doses. My patient told me she could not take quinine, but I thought I would risk it. The result was that after she had taken two doses her skin turned a bright scarlet, her eyes became congested, and she complained of an intense itching and burning, with extreme nausea and vomiting. Her temperature rose to 103°. By the next day, all the symptoms had disappeared. I have read of such cases, but this is the first time I have seen one in my practice, which is in a malarial country, at that.

Yours truly, B. D. Talbott, M. D.

Birdville, Texas,
June 15, 1888.

The Attire of Women.

To the Editor.

Sir: The Israelitish women, after they had left Egypt, were forbidden to wear men's clothes. The style is not mentioned.

Yours truly, Edw. Vanderpoel.

New York, June 15, 1888.

NOTES AND COMMENTS.

American Rhinological Association.

The American Rhinological Association will hold its sixth annual meeting at Cincinnati, Ohio, September 12, 13, and 14, 1888.

Communications in regard to this meeting may be addressed to

Dr. John North, Secretary,
Keokuk, Iowa.

Epidemic of Typhoid Fever.

At the meeting of the Society of Public Medicine and Professional Hygiene of Paris, March 28, 1888, M. Napias (*Bulletin Médical*, April 22, 1888), spoke of an epidemic of typhoid fever which had broken out in an institution for blind children in Paris. It seems from his statement that the disease had been in the neighborhood for some time, but the first case developed in the institution November 12, 1887. There were fourteen cases altogether, and two deaths, a mortality of 14.3 per cent. Thinking that the cause of the epidemic should be sought in the water-supply, he had this changed by December 20. The last case of typhoid appeared January 6, 1888, eighteen days after the change of water-supply.

The checking of the epidemic by the change of water-supply is the chief point of interest in this report of M. Napias. It gives force to the advice which cannot be too often repeated: In any epidemic of typhoid fever in which the source of contagion is not obvious, examine most carefully into the character and source of the milk and of the water supply.

Laceration of the Vulva after Child-Birth.

At the meeting of the Society of Practical Medicine of Paris, April 12, 1888, M. Auvard reported the following statistics bearing upon the condition of the vulva following child-birth, and based upon the examination of one hundred cases observed by him at the Charity Hospital:

The vulva was intact in five per cent.; the perineum was more or less torn, with integrity of the rest of the vulva, in fifteen per cent.; lateral or upper portions of the vulva were torn, with integrity of the perineum, in thirty per cent.; vulva and perineum were injured in fifty per cent. In view of the great frequency of injuries of the vulva, and the consequent danger of the penetration of germs into the system, Auvard advises careful antisepsis.—*Bulletin Médical*, April 15, 1888.

Guaiacol in Tuberculosis of the Lungs.

The use of guaiacol in phthisis has been spoken of in the REPORTER a number of times. We learn from the *Wiener med. Presse*, May 13, 1888, that Dr. Horner has recently stated in the *Prager med. Wochenschrift*, No. 17, 1888, that he is much pleased with the results obtained by him in its use during four years. The patients took it willingly, and after the first few weeks their appetite markedly increased, the cough and the quantity of the sputum simultaneously diminished, sleep was undisturbed, the strength and body-weight increased, and the night-sweats diminished or wholly disappeared. With these general signs of improvement in the disease, there was also a decrease in the fever. When guaiacol had been continued longer, the râles disappeared more and more, while percussion no longer revealed the exact borders of the affected lung; moreover, the number of tubercle bacilli became fewer or wholly disappeared, the drug having such a decided influence upon these excitors of the disease, that a patient with beginning tuberculosis of the apices may become entirely cured after several weeks' treatment. Horner orders the guaiacol in pills containing about one grain each. He begins with three a day, increases this after three days to six, and again after three days to ten, and directs them to be taken immediately after breakfast, dinner, and supper. In addition, the patients are well cared for and nourished and placed in pretty good hygienic conditions.

Experimental Nephrectomy.

At a recent meeting of the Anatomical Society of Paris, M. Tuffier stated that he had undertaken some experiments to determine the minimum quantity of kidney substance which is necessary to life. After a total right nephrectomy, he had performed two partial left nephrectomies upon a dog, from which he at once recovered. The resected kidney quickly cicatrized, and the loss of substance has in great part been filled in by epiploic adhesions.—*Bulletin Médical*, May 2, 1888.

Peculiar Case of Dermatitis Due to Antipyrine.

In the *Therapeutische Monatshefte*, No. 9, 1888, B. Spitz reports the case of a young man who had taken one hundred and thirty-five grains of antipyrine within one week during an attack of typhoid fever. As the seeming result of the drug, there suddenly developed over his whole body an eruption which at first was like that of measles and subsequently more like that of scarlet fever. On the face there were elevations resembling urticaria; the eyelids and lips were swollen and very œdematous. After a bath, which was taken on the fourth day to hasten the desquamation which was already beginning in the form of large leaves, the epidermis over the whole body separated in large shreds, a moist surface remaining. Here and there were blisters containing serum, and larger than a dollar. These burst on the gentlest touch; but in other places it was sufficient to stroke the skin gently with a finger to loosen the whole membrane. Recovery occurred slowly under the use of a powder which was dusted on.—*Centralblatt f. d. med. Wissenschaften*, May 12, 1888.

Transplantation of the Cornea.

Dr. J. J. Chisolm has performed Von Hippel's operation of transferring a piece of rabbit's cornea to a man's cornea at the Presbyterian Eye, Ear, and Throat Charity Hospital, Baltimore. The patient had been blind for many years. A piece of the blind eye was cut out with a trephine driven by clockwork. With the same instrument, a duplicate piece was taken from the sound eye of a living rabbit and fitted accurately into the hole made in the man's cornea. The operation was made painless by the use of cocaine. This operation, it will be remembered, has been already referred to several times in the REPORTER.

Honoring Dr. Corson.

In honor of his sixtieth year of practice, Dr. Hiram Corson, of Conshohocken, was tendered a reception in the Bellevue Hotel, Philadelphia, June 6, 1888. The doctor is in his eighty-fourth year, and is the oldest living graduate in medicine of the University of Pennsylvania.

Effects of Exposure of the Intestines.

At the November meeting of the Berlin Obstetrical and Gynecological Society, Professor Olshausen read a communication on a hitherto unrecognized cause of death after laparotomy at which intestine has been allowed to lie outside the abdominal wall for a prolonged period. In this country, says the *British Medical Journal*, May 19, 1888, surgeons are careful to prevent prolapse of the intestines. Coils which adhere to a tumor and cannot be at once separated are carefully covered with flat sponges or with towels wrung out of hot water, which often contains an antiseptic compound. As soon as the adherent coils are separated from the tumor, all bleeding points being secured, they are carefully replaced. As soon as the tumor is extracted through the abdominal wound, or indeed whilst it is slipping out of the incision, a broad flat sponge is slipped into the peritoneal cavity to prevent any chance of prolapse and to protect the gut from the suture-needles. The abdominal incision is, moreover, always made as short as possible, so as to avoid the sudden escape of coils of intestine. The Germans are less particular about eventration. Dr. Martin, in 1885, publicly recommended the dragging-out of a large amount of intestine in cases in which the tumor lay deep in the abdominal cavity, and declared that the greater part of the intestinal tract might be left hanging out of the abdomen during the whole operation, so that the surgeon might have plenty of room for manipulating the tumor. "This eventration," said Dr. Martin, "is quite free from danger; I have practiced it in at least ninety per cent. of my cases without seeing any evil results." Professor Olshausen was more cautious, and directed attention to certain cases of collapse, often fatal, which followed cases of abdominal section and were not accompanied with symptoms of peritonitis. He concluded that prolonged exposure of the intestines in laparotomy might cause disturbance in the circulation in the walls of the gut, ending in venous stasis and serous infiltration, with ultimate formation of ecchymoses. At the same time, the muscular coat is paralyzed, often for several days; if the paralysis does not abate, symptoms of ileus set in. Fatal results of this kind are probably caused by the absorption of decomposing material in the intestinal canal.

Another objection to exposing the intestines is that it results in great loss of heat. Special stress is laid upon this point by Prof. Ashhurst (see REPORTER, April 7, 1888), who, it will be remembered, attributed much of his success in many serious operations to his care in preserving the body-heat.

Hyoscine.

Budde's results obtained in the Friedrichshain Hospital under the direction of Fürbringer, are in essential agreement with those of Erb. He found that hyoscine was more active than hyoscyamine, and employed the iodate of hyoscine hypodermically in solutions of one part in one thousand of water. The initial dose for adults was 2-10 milligram (1-325 grain); for children, 1-10 milligram (1-650 grain). His results are as follows (*Deutsche med. Wochenschrift*, May 17, 1888): The drug has no direct effect in controlling muscle-spasm, the movements of chorea minor and athetosis, nor does it exert any direct influence upon whooping-cough; its hypnotic action in cases of tabes is but slight. Partly successful results were obtained in the night-sweats of phthisical patients and in lead-colic; its action upon the perspiration and salivary secretion is as variable as that of atropine. Its effect is most prompt in the trembling of paralysis agitans, and in senile and alcoholic tremor. In these cases, hyoscine also acts favorably upon the sleep of the patients, often in cases in which other hypnotics have either entirely failed or are only partly successful. Its effect upon trembling is not, however, lasting. An important effect produced by it is fatigue, which is always observed; other secondary effects are scintillations before the eyes, dizziness, dryness in the mouth and throat, thirst, dilatation of the pupil, and delirium. In one adult, disagreeable secondary symptoms were noticed after 1-325 grain, while in some children this dose was borne without producing these symptoms. The largest dose given to an adult was 1-93 grain, and it produced serious secondary symptoms. If hyoscine is given for a long time, the patient becomes accustomed to it, and the dose has to be increased to bring about the same effect.

Treatment of Furuncles in the External Ear.

In a communication to the *Berliner med. Wochenschrift*, April 30, 1888, Grosch praises the effect of acetate of aluminium, freely diluted with water, in the treatment of furuncles in the auditory canal. He fills the canal full of the solution and then closes it with cotton. If the furuncles have already gone to the point of fluctuation, they are first evacuated by an incision. The result has been highly successful, even when both canals have been affected with diffuse furunculosis. In at most four hours after the application has been made, the pain became bearable; after perhaps eight hours, it had pretty nearly completely disappeared. After a few days—from two to six—complete recovery occurred in all the cases. No new furuncles, nor any granulation formation, occurred. Furuncles which were still quite firm disappeared without going on to suppuration; those in which pus had begun to form healed through inspissation of the pus and reabsorption. The use of the remedy in such strength as was employed occasioned no injury—at most, occasional temporary itching.—*Wiener med. Presse*, May 13, 1888.

Dangers of Antiseptics.

At the last meeting of the Berlin Medical Society, says the *British Med. Journal*, May 19, 1888, Dr. Emil Senger read a paper on the influence of antiseptic remedies on the organs of the body, with special reference to operations on the kidney. It is well known that after nephrectomy, or even nephrotomy, many patients die with symptoms of uræmia or anuria, even when it had been ascertained beforehand by careful examination that the other kidney was quite healthy and capable of secreting the necessary amount of urea. Dr. James Israël, chief surgeon of the Berlin Jewish Hospital, has propounded a very complicated theory as to certain nervous sympathies between the two kidneys, whereby an operation on one may give rise to degeneration of the other. Senger has now proved by experiments on rabbits and dogs that our antiseptic remedies are the cause of these complications. He injected into the animals, when in perfect health, one tenth or twelfth part of the quantity of corrosive sublimate, carbolic acid, etc., which is sufficient to kill them. He then extirpated one kidney, and examined it microscopically, with the result that in all cases he found glomerulo-nephritis. There was exudation between the glomerulus and the capsule, and the epithelium of the tubuli contorti was almost entirely destroyed. He found also fatty degeneration of the liver, the spleen, the heart-muscle, etc. The various antiseptic agents were found to be injurious in different degrees, corrosive sublimate being the most dangerous, then the others in the following order: iodoform, carbolic acid, salicylic acid, boric acid. Senger therefore recommends surgeons to avoid antiseptics in operations on the thorax and abdomen, and urges them either to employ sterilized water or a solution of salt. By bacteriological and pathological researches he proved, first, that this kills the streptococcus pyogenes aureus in twenty-eight minutes, and that the effect is independent of the degree of concentration, for a five per cent. solution is just as effectual as a twenty per cent. Secondly, he claims to have shown that chloride of sodium does not in any way injure the organs, and that no dose is strong enough to kill any animal.

Aneurism of the Femoral Artery.

At a recent meeting of the Surgical Society of Paris, M. Bucquoy related a case of aneurism of the femoral artery treated according to the method recommended by Baccelli. A woman about forty years old came to the hospital with a tumor seated at the origin of the femoral artery, which, by examination, was found to be an aneurism. The heart showing symptoms of valvular disease, M. Bucquoy hesitated to tie the external iliac artery, and in this disposition he was encouraged by one of his colleagues. Electro-puncture was resolved on, but the pain was so great that this method had to be abandoned after two trials. He sought then to obtain coagulation of the blood by the introduction of a foreign body, and with this view he introduced the spring of a watch, as advised by Baccelli. The spring went in without difficulty, but, instead of curling up, it went through the opposite wall; being slightly withdrawn, a portion was cut off, leaving about an inch and a half in the sac. During the following days the pain diminished, and the tumor became much firmer. Two months afterward, the patient, having fallen into a cachectic state, died. When the tumor was opened, the spring was found broken and covered with fibrin, but the clots were of recent formation. However, M. Bucquoy thought that, on the whole, the patient was benefited by the treatment, and that it might be repeated in a similar case.—*Medical Press and Circular*, May 16, 1888.

Treatment of Ingrowing Nail.

A very simple treatment of ingrowing nail is proposed by Patin in the *Gazette des Hôpitaux*. After cleansing and disinfecting the affected nail, the parts between the nail and the granulations are painted with a solution of traumaticin, which consists of one part gutta-percha to eight of chloroform; this painting is done at first a number of times a day, but later less frequently. The foot is protected somewhat, and by degrees the nail lifts itself from the tissue in which it was imbedded; it may then be removed without pain with scissors. Traumaticin acts as an anæsthetic by virtue of the chloroform, and mechanically through the gutta-percha, which insinuates itself between the nail and the granulations, and so frees the former from the ingrowing tissue.—*Wiener med. Presse*, May 6, 1888.

Bad Prescribing and Still Worse Dispensing.

The *Ephemeris*, June, 1888, says: The writer was recently summoned as a witness in a New York Court, and heard the following case: A physician gave a patient, for colic, one-third of a grain of sulphate of morphine by hypodermic solution in the walls of the abdomen, and gave him a prescription for "Mistura Squibb 2 ℥," to be taken as directed. The verbal directions given with this were that if, on reaching home, the man's pain was better, he should take none; if about the same, take a teaspoonful; if worse, take two teaspoonfuls. In a few minutes after the man left it, the pharmacist came to the physician's office to ask what "Mistura Squibb" was, or what was meant by it. The physician gave him the formula for the common compound tincture of opium, or diarrhœa mixture. He knew what that was, and went off to dispense it. A short time after, he came to the physician again, and said he had made a great mistake by having dispensed the compound solution of opium, a preparation six times stronger than that intended, and containing a proportion of opium equivalent to about 7½ grains of sulphate of morphine to the fluidounce.

They at once sent for the patient to come to the pharmacist's store, when they found he had taken two teaspoonfuls of the compound solution of opium, about equivalent to two grains of sulphate of morphine, after having had one-third of a grain by hypodermic injection. The gravity of the case was at once realized, and very vigorous proper measures were adopted to counteract the opium; and, after two physicians walking and dragging the patient through the streets all night, with occasional bowls of strong coffee—keeping near to a large hospital where a battery was in readiness in case the respiration should entirely fail—signs of improvement began. Then in a few hours more the danger was past.

It seems altogether inexcusable for any physician to write such a line as that above quoted and issue it as a prescription, because it really indicates nothing, and means nothing that any pharmacist is bound to know, or can in any way be responsible for not knowing. If physicians by thoughtless habits abbreviate and curtail their names so that they signify nothing with definiteness or safety, and will use names of persons instead of things, or proper names as indefinite adjectives, they not only discredit themselves, but also their profession, and when they get into the Courts they can expect no mercy.

The pharmacist in this case did exactly what was right, and took the only proper course open to him, when he went to the physician with his nondescript prescription for an explanation, and the physician then did the best he could do by giving him the formula for it. But, after this, the pharmacist went back and committed the almost criminal blunder of dispensing a solution instead of a tincture, the one six times stronger than the other—with the formula for the weaker one in his hand, and the label of the stronger one on his bottle—with a nearly fatal result.

Lanolin in Cuts and Burns.

A recent article in the *Pharmaceutische Rundschau*, March, 1888, states that experience has shown that lanolin is an excellent dressing for cuts and burns. Professor B. Fränkel finds that it prevents the formation of scabs, and that burns under this treatment do not desquamate so much as under most others. In cases in which it is desired to irrigate a wound, in order to reduce heat and irritation, lanolin may still be applied, as it is not readily washed away. If a small wound is immediately dressed with this ointment basis, hemorrhage is stopped.—*British Med. Journal*, May 19, 1888.

—It is announced that the Queen has given $350,000—the balance of the Women's Jubilee offering—to St. Catherine's Training Hospital for Nurses for the London poor.

Lung-Cavity injected with Carbolized Iodine.

Dr. E. Peyre Porcher, in reporting a series of cases in the *New Orleans Med. and Surg. Journal*, June, 1888, gives the following particulars of a case in which he injected carbolized iodine into a lung-cavity. This case was interesting, he says, as it at least demonstrated that very slight disturbance, either local or general, may result from such a procedure. M. White, colored, thirty-five years old, was admitted July 10, suffering with a phthisical abscess in the left lung, associated with cough, purulent expectoration, night-sweats, and other symptoms of well-marked pulmonary disease. The cavity was single and so extensive and well-defined as to render it extremely suitable for injection. The formula recommended by Dr. Blake White of New York was employed, which is as follows:

℞	Atropia	gr. ⅓
	Morphia sulphate	gr. iv
	Tinct. iodine	f℥ iii
	Acid. carbolic (pure)	gtt. xx
	Glycerine	f℥ ss
	Dilute alcohol, 20 to 30 per cent.	f℥ ss

M. Sig.—15 to 30 minims.

His needle attached to a hypodermic syringe filled with the fluid was used. The fluid was injected into the left lung at a point about two inches below the clavicle, and the same distance from the left border of the sternum. When the point of the needle passed in and touched the posterior wall of the cavity, the resistance was easily felt, and he could be certain of the success of the operation.

With the exception of some cough, there was so little irritation, pain, or uneasiness produced, that the patient was not deterred from going almost immediately to a meal. Nearly every disagreeable symptom was relieved and the cough greatly diminished. The operation was repeated after six weeks, but did not arrest the final advance of the disease, though the patient survived several months.

A similar case, Dr. Porcher says, is reported in a previous series of cases.

Meco-Narceine.

In the group of substances obtained from opium is found one, which, without possessing the toxic properties of the other opium preparations, exhibits pronounced narcotic action. This substance is narceine. But its use is rendered difficult by the fact that it is difficult to make, and when made is insoluble in water. Laborde now offers a preparation of opium which is free from morphine, and consists of narceine to which some unknown alkaloid clings. This preparation, which Laborde calls meco-narceine, possesses pronounced narcotic power, without acting as a poison. When one or two centigrams (grain one-sixth to one-third) are injected into a dog weighing ten or twelve kilograms, the animal falls into a quiet, deep sleep, from which it wakes fresh and cheerful—unlike the after-effect produced by morphine. Meco-narceine produces a diminution of the general sensibility, which is not observed after the use of pure narceine. When meco-narceine is freed from the unknown alkaloid which clings to it, chemically pure narceine is obtained, which is insoluble and does not possess the good properties of meco-narceine. The slowing of the respiration and circulation produced by meco-narceine, as well as the fall in arterial blood-pressure and in temperature, shows that a certain degree of anæmia of the nerve-centres is the cause of the effects produced. Laborde employed meco-narceine in the form of pills containing one-twelfth to one-sixth of a grain, by hypodermic injection (one-twelfth of a grain to about fifteen minims), and in the form of a syrup in the proportion of one-sixth of a grain to three-fourths of a fluidounce. He regards the chief indications for the use of the drug as sleeplessness, bronchial affections in which cough and secretion form the chief symptoms, neuralgia, and as a substitute for morphine in morphine-takers. The dose may be increased without harm up to one-third, one-half, and even two-thirds, of a grain a day.—*Wiener med. Presse*, May 27, 1888.

A Bullet which had passed through the Abdominal Wall discharged per Anum.

Dr. J. O. Stewart, of Cedarville, O., reports the following case in the *Medical Record*, June 2, 1888: Laura B——, sixteen years old, colored, was shot August 2, 1887. The ball, which weighed sixty-eight grains, penetrated the abdomen to the right and a little above the umbilicus. The opening made by the ball was round, and was not probed beyond a depth of one inch. The wound was washed with water containing carbolic acid, and absorbent cotton with adhesive plaster applied. The patient rallied well from the shock. The treatment was directed toward absolute rest. The bowels moved eighteen days after the accident. Urine, during this time, was dark and con-

tained a substance like coffee-grounds. The patient vomited occasionally during the whole time of her confinement to bed, which was about three months, and at times the vomited matter contained a little blood. Her temperature frequently was as high as 105°, and was kept down by antifebrine administered freely, in doses of about five grains every three to five hours. The ball was passed per anum on the thirty-sixth day. It was considerably altered in shape, and was indented in several places.

The Treatment of Acne.

Dr. P. G. Unna, in the *Monatshefte für praktische Dermatologie*, writes: "As every ordinary suppuration must be regarded as due to the invasion of pus microbes, so the clinical picture of acne divides itself into two essentially distinct sections. These are, the process of follicular obstruction and of the formation of comedones, and the process of suppuration in the follicle. Comedones are often erroneously separated from acne; their sole cause is the abnormally firm coherence of the horny layer on portions of the skin provided with lanugo hairs. Whether this change in the horny layer is due to a partial anæmia of the skin, or to the presence of special organisms, is not known. The second part of the process, the suppuration of the follicle, takes place only in those plugged glands within which pus microbes have entered before their closure, and which have been subjected subsequently to irritation (mechanical, eczematous, or from tar, chrysarobin, iodine, or bromine), which has facilitated the intrusion of the pus microbes into the follicular walls. Thus the treatment of acne has to fulfill two chief indications—to loosen the corneous layer and to destroy the microbes. The horny layer can be best removed slowly by means of sulphur and resorcin, while the hyperæmia associated with all efforts at reducing cornification is lessened by the application of oxide of zinc. Resorcin has this advantage over sulphur, that corrosive sublimate, the best agent for destroying micro-organisms, can be combined with it; carbolic acid, on the other hand, goes best with sulphur. Twice or thrice a week the whole surface should be gently scraped, the pustules punctured, and the comedones pressed out. The effect of treatment should be observed at frequent intervals. Every acne patient must wash with soap, and employ water as hot as he can bear, in order to soften the horny layer. Hebra's spirit of soap, marble soap, or sublimate of mercury soap, are still better than common soap. Sensitive persons may dust with oxide of zinc and starch after washing, since this does not occasion any blocking of the follicles. Pastes suit for application at night best, while lotions and spirituous applications can be used in the daytime to maintain their effect." As examples of suitable prescriptions, the following are given:

Sulphur paste at night and resorcin spirit during the day.

℞ Ung. zinci benzoati, ... ℥ iii
Sulphuris precipitati, ... ℥ iiss
Terræ siliceæ, ... ℥ i
[*vel* kaolini], ... ℥ ii¼
M. f. optime terendo pasta.

℞ Resorcini, ... ℥ ss-℥ i¼
Glycerini, ... ℥ ss
Aq. flor. aurant., ... ℥ v
Spiritûs, ... ℥ iiss
M. Signa. The lotion.

Together with this either spirit of soap, or over-fatty marble soap, to wash with.

Resorcin paste at night and corrosive spirit during the day.

℞ Ung. zinci benzoati, ... ℥ iiss
Resorcini purissimi, ... ℥ iiss
Terræ siliceæ, ... ℥ iiss
[*vel* kaolini], ... ℥ v
M. f. optime terendo pasta.

℞ Hydrarg. bichloridi, ... gr. $\frac{5}{6}$–⅓
Glycerini, ... ℥ ss
Aq. flor. aurant., ... ℥ v
Spiritûs, ... ℥ iiss
M. Signa. The lotion.

Together with these either spirit of soap, or over-fatty sublimate soap, to wash with.

When the disease has been removed by the treatment indicated, resort must be had to procedures calculated to obviate recurrences. To this end, the continuous employment of a weak resorcin paste, or of a spirit containing 2 per cent. of resorcin and 1 per 1000 of corrosive sublimate, or the regular use of sublimate soap, or of marble soap for the face, will be found beneficial. In addition, as in every parasitic affection of the face, any pityriasis capitis must be cured, since in it there is a lurking-place of those germs which are liable to grow in the skin. This simple prophylaxis will prevent many recurrences. Arsenic and ichthyol internally act favorably on the parakeratosis, while keratinized pills, containing one-seventh of a grain of sulphide of calcium, promote suppuration in the follicle.—*Edinburgh Med. Journal*, May, 1888.

—Dr. F. Loeffler, staff-surgeon and *privat docent* in the University of Berlin, has been appointed to the Professorship of Hygiene in the University of Greifswald.

Death from Ether in Hamburg.

Dr. A. C. Bernays, in a letter from Hamburg to the *St. Louis Med. and Surg. Journal*, June, 1888, says: "Kümmel is not *the* great surgeon here, but, with all that, he is a man of considerable and deserved reputation. The greatest man here is Schede, and I have spent most of my time in his hospital. Dr. Sands, of New York, spent a month with Schede, and, being a partisan of ether as against chloroform, he undertook to convert Schede by showing him how to use the former anæsthetic. The case was that of a woman of about thirty-eight, afflicted with uterine cancer. Sands, who as you know is recognized as one of our best American surgeons, sent to London and got an ether-bag and the apparatus necessary for the administration of the anæsthetic, and also secured an article of the very purest and best in the way of ether. He and his son, Dr. Sands, Jr., began the administration in the presence of Schede and eight other prominent surgeons. In less than four minutes, the patient was dead—so very dead that all means at revivification—artificial respiration, even tracheotomy and forced air, were of no avail. The post-mortem showed normal heart, lungs, and brain—in short, nothing abnormal or pathological but the cancer of the uterus.

"The French and Germans, as you know, have never taken kindly to ether, using it but very little, and, if this incident will keep them from using it at all in the future, they are to be congratulated. I cannot, myself, understand how anybody who has ever used chloroform can become a convert to ether. It takes a good deal of prejudice even to make those who have been its advocates stick to it, and I am glad to say that all of my observations and experiences of this trip tend to show that it is gradually going out of use abroad. Take the world over, and chloroform is now administered five times where ether is resorted to once. There have consequently been a few more deaths, in the gross, accredited to chloroform within the past year, over those attributable to ether; but, when the number of times each was used is taken into consideration, ether has been far the more fatal. I think chloroform is dangerous only when there is grave organic disease of the heart, or in persons addicted to whiskey."

—The will of Dr. Rachel L. Bodley bequeaths her scientific books to the Women's Medical College of Pennsylvania.

NEWS.

—Professor Fürbringer, of Amsterdam, has been suggested for the chair at the University of Jena made vacant by the call to Berlin of Professor Hertwig.

—Dr. Ludwig Knorr has been appointed Extraordinary Professor of Chemistry at the University of Würzburg.

—Professor Celli, of the University of Rome, has proposed to establish a number of meteorological stations in the malarious region encircling Rome, for the special study of the fever and its climatic conditions. The proposal has been favorably received by the Roman authorities, and the stations will be located without delay.

—At the celebration of the 800th anniversary of the University of Bologna, June 13, the degree of Doctor of Medicine was conferred by the University upon S. Weir Mitchell, of Philadelphia, and upon Sir Spencer Wells, of London. Mr. Huxley received the degree of Doctor of Science.

—Dr. B. E. Hadra has accepted the chair of Surgery in the Texas Medical College, and has removed to Galveston.

—Dr. Karl Kilcher, assistant in the Bohemian Laboratory of Pathological Anatomy, died of blood-poisoning, which he suffered while investigating the blood of typhus-fever patients.

—Dr. Squibb says that a very good way to give iodine is by inhalation of iodide of ethyl. Iodine is found in the urine within fifteen minutes after the same number of inhalations.

—Dr. Clara Marshall has been appointed Dean of the Women's Medical College of Pennsylvania.

—Prof. J. Hyrtl, of Vienna, has given six scholarships for medical students, open to students of all nations.

—The *Maryland Med. Journal*, June 16, 1888, states that Dr. George W. Miltenberger, of Baltimore, has met with a painful accident. As he was coming downstairs he fell, breaking the tendon of the quadriceps femoris of the right leg, just above the patella. Dr. L. McLane Tiffany put the injured leg in a plaster-of-Paris splint. Dr. Miltenberger is said to be getting along very comfortably, and, while his injury may be more painful and tedious on account of his advanced age (sixty-nine years), his physician and family hope for a rapid recovery. Nothing more serious than a possible stiffness is anticipated.

—Dr. Burke, an English physician who shot and killed his nine-year old daughter and afterward tried to shoot himself, has been reprieved after being sentenced to death. This was in accordance with a petition signed by many English physicians.

—The *Western Druggist*, June, 1888, says that on account of the serious inconveniences from the use of the copyrighted term antipyrine, which only describes one property of the drug so designated, it will hereafter be called "methozin" in the columns of that journal. This term is simply a diminutive of its chemical title.

—There is to be a Medical College in Memphis called the Jay Gould Medical College.

HUMOR.

CONCLUSIVE EVIDENCE.—"Doctor, I hear that Brigsby has started a new paper." "So I am told, but I haven't seen a copy." "He told me the other day it would be bold and aggressive. I wonder if it's that kind of a sheet?" "I guess it is. I sewed up a scalp-wound for him this morning."—*Lincoln Journal.*

I TOLD YOU SO.—Brown: "You don't look very happy, Robinson." Robinson: "No, I left off my flannels this morning and caught cold." Brown: "That's bad." Robinson: "Oh, I don't care anything about the cold; but my wife told me I was leaving them off too soon."

A HAPPY MAXIM.—"'Onward and upward' will be the maxim of the new paper," said the editor, proudly. And it proved a happy maxim, too. For three short months the paper went onward, and then it went upward.—*Harper's Bazar.*

HUSBAND: "What does the doctor say about your new maid, my dear?" Wife: "He says that there is but slight chance of her recovery, and she promised to be such a treasure. I declare, it's too provoking for anything!"—*The Epoch.*

RECENTLY THE NEWSPAPERS have told the story of a man whose foot was crushed in an accident and had to be cut off, after which death relieved his sufferings. All the accounts closed by saying that the operation by Dr. X. was successful; but, a few days later, blood-poisoning set in, which proved to be fatal. This reminds one of a great man of the last century whom Mesmer boasted of having saved, although he died on his hands. "He died," cried Mesmer, "but he died cured."—*N. Y. Evening Post.*

CORRECT DIAGNOSIS.—Doctor (feeling patient's pulse): "What is your husband's business?" Patient's Wife: "He is a photographer." D.: "Has he been working hard of late?" P. W.: "I don't know, doctor. He took the portraits of four babies yesterday." D.: "H–m! Brain-fever."—*Boston Post.*

HOW IT WORKS.—Bobley—I hear they've been trying the faith-cure on Jawkins. Wiggins—Yes, it's a great thing for rheumatism. Bobley—Indeed! Is he stronger? Wiggins—No; but the rheumatism is. It's got him all twisted up in a hard knot now.—*Judge.*

A SMALL BOY, required to write a sentence containing the word "hominy," produced the following: "Hominy marbles have you?"—*Boston Transcript.*

OBITUARY.

PROFESSOR L. M. POLITZER, M.D.

Dr. Politzer, the eminent professor of pediatrics in the University of Vienna, Austria, died May 23. He was born in Arad, Hungary, in 1814, and obtained his degree in medicine at Buda Pesth and Vienna in 1839. In 1875 he received the title of professor, and in 1880 he was intrusted with the management of the first public hospital for diseases of children in Vienna. In June, 1853, he, together with Mayer and Schüller, started the famous *Jahrbuch für Kinderheilkunde*, to which he contributed many valuable papers.

HOWARD PINKNEY, M.D.

Dr. Howard Pinkney, a well-known surgeon, of New York, died (as we stated in the REPORTER, May 26) on May 14, on a train, while traveling from Southampton to London, England. His funeral took place June 11, at the Church of the Holy Trinity, New York. Dr. Pinkney was graduated at the College of Physicians and Surgeons, New York, in 1860. He was a member of the New York County Medical Society and of the Academy of Medicine, and was one of the surgeons to the New York Eye and Ear Infirmary.

DR. E. GARDETTE.

Dr. Emil B. Gardette, the President of the Board of Trustees of the Jefferson Medical College, died June 17, 1888, at his residence in Philadelphia, in the 85th year of his age. He was graduated from the Jefferson Medical College in 1838, and subsequently became well known as a dentist.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental and Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Clinical Lecture.

INFANTILE LEUCORRHŒA.

BY A. REEVES JACKSON, A.M., M.D.,
PROFESSOR OF GYNECOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO, ILLINOIS.

(*Reported by William Whitford, M.D.*)

Gentlemen: This little girl is eight years of age. About two weeks ago, there was noticed for the first time a discharge from her genitals. It was thin, yellowish, and produced excoriation of the labia. Attention was called to her condition by the fact that the child was observed to scream with pain whenever she passed urine, and would at the same time carry her hands to the parts. On examination of the latter by her guardian, the external genitals were seen to be red, and the discharge was oozing from within. Portions of the latter were also smeared upon the child's clothing.

Now, as I expose the parts, you may notice the patchy redness of the skin about the lower parts of the vulva, and extending almost to the anus. As I separate the labia, the redness within their border is seen to be still more intense and to cover their entire inner surface, and also that of the vestibule and the urinary meatus. This is what is termed *infantile leucorrhœa*, and, inasmuch as it differs in some respects from the disorder as it occurs in adults, I desire to call your attention to its peculiarities.

Although termed *infantile* because it frequently is seen in children three or four years of age or even younger, it may present its peculiar features when its subjects have attained the age of twelve or thirteen. It differs from the leucorrhœa of adolescence or maturity especially in two respects—namely, first, in the character of the discharge; and, second, in its locality. The discharge is serous, or purulent, or composed of a mixture of serum and pus, and its seat is the vulva. The leucorrhœas of the adult consist very largely of mucus and vaginal epithelium, with more or less admixture of sebaceous matter; but the vulvar mucous and sebaceous follicles are not developed in childhood, and hence these elements are absent from the discharge of infantile leucorrhœa. Then again, it is rare to find the source of this latter disorder above the hymen.

Very frequently the subjects of this disease are strumous, sometimes the victims of hereditary syphilis, and they are predisposed to it just as they are to certain forms of cutaneous eruption, tuberculosis of the joints, and glandular enlargements. In such children, lack of cleanliness or of other proper hygienic surroundings is sufficient to act as an exciting cause and to induce the discharge. The latter is always acrid, and produces at first itching, then pain, and the child's fingers by their scratching and rubbing add to the irritation, and soon inflammation of the skin and mucous membrane is set up or increased.

There seems to be a popular belief that this disease is very frequently the result of attempts at coition, and suspicion is likely to be fastened upon someone, justly or unjustly—usually, I am glad to say, the latter. In such case, you may be appealed to for your opinion—based, probably, upon that of a prejudiced mother or other relative. Be on your guard. Do not commit yourselves hastily, or you may do someone grave injustice. The courts have held that the

existence of leucorrhœa in a child is not even presumptive evidence of any impropriety or crime, and that the latter, if charged, must be proved by other and wholly independent evidence.

Leucorrhœa in children may be a sequel of acute exanthematous diseases, as smallpox, scarlatina, measles. Ascarides have been accused of traveling from the rectum to the vulva, and settling down there to cause itching and make trouble, but I have never caught them doing so. I knew one little girl in whom a severe purulent discharge was caused by the presence of a half-dozen small pebbles which she had pushed into the vagina.

The treatment is indicated by the pathology of the disease. For cases in which there is evident impairment of or feeble vital power, what is known as general treatment will not only constitute an important, but a necessary, element. Thus, in strumous children, you will need to secure improved digestion and assimilation by the aid, perhaps, of cod-liver oil, iron, cinchona, and still better, if possible, an abundant supply of nutritious food. Another important adjuvant is cleanliness. Usually the subjects of this disease are found with filthy environment, where cleanliness is practically unknown, and a bath for the entire person never taken. But, in addition to these means, local treatment is always necessary. And, before this is commenced, a very careful examination of the parts should be made, in order that one may be assured that neither ascarides nor pebbles are present to maintain mischief. In this case, I fail to find anything of this sort, and, as the child presents an appearance of good general health, and the disease has a short history so far as is known, we may conclude that the cause of the latter has been acting only recently. The treatment will be simple; cleanliness must, first of all, be insisted upon. The parts should be carefully cleansed by separating the labia and gently mopping away the secretion with a piece of absorbent cotton, which may be used dry or moistened with a solution of borax in water—one drachm to a pint. Soap is frequently irritating. Then, after drying the surface, a small pledget of cotton covered with vaseline and freely sprinkled with boracic acid should be placed between the labia. Instead of boracic acid, iodoform, or subnitrate of bismuth, or powdered borax may be used. The cleansing and the renewal of the dressing ought to be done two or three times daily. The objects of this treatment are to soothe the affected surfaces, to absorb the discharge, to prevent the possible adhesion of opposing abraded surfaces, and to protect them somewhat from the access of atmospheric air, the latter being sometimes a source of pain. Under this treatment assiduously conducted, I would expect this little patient to be well in eight or ten days.

COMMUNICATIONS.

SUDDEN DEATH DURING OR FOLLOWING LABOR.

BY THEOPHILUS PARVIN, M.D.,
PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN, JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

Whether one believe with the Roman Emperor that the death which is most sudden is that most to be desired, or place it, as is done in the rubric familiar to all, at the climax of earthly calamities, such event is always startling, and usually most painful to the witnesses. This pain is greatest, the misfortune almost without exception the gravest, if a mother dies in childbirth, or soon after. Many causes conspire to make such an event peculiarly sad. The abrupt severing of new ties, the loss of life in giving life, the sharp contrast between an infant living and a mother perishing just when the former so greatly needs the loving care of the latter, are among these causes.

The obstetrician not infrequently suffers public reproach when such an event occurs in his practice, for people are slow to understand how that which is in the majority of cases a simple physiological process may have a fatal issue. Moreover, in some instances, death can be averted if the practitioner, forewarned of its imminence, uses appropriate means; in others, the prophecy of such event as possible, probable, or inevitable may protect his reputation; and in still other cases, if prophecy should fail—the event coming unexpectedly to him as to others, casting no shadow before it—his ability to explain its cause is very important. It is therefore alike the duty and the interest of the obstetric practitioner to study carefully the causes of sudden death in childbirth and in the first part of childbed.

Constant supply of oxygen to the organism, and the regular distribution of blood suitable for nutrition, are the two essentials for the continuing of life—in other words,

the lungs and the heart must perform their respective functions, and thus the tripod of Bichat is replaced by a biped, for the brainless fowl lives, though it instantly perishes if deprived of heart or lungs. In most cases of sudden death, the heart, the *ultimum moriens* of Galen, first stops—or, in other words, death is caused by syncope, not by asphyxia. If death begins at the lungs, the fatal event is usually slow in progress; nevertheless, it may then in some instances be sudden, as from pulmonary embolism, just as, on the other hand, cardiac death does not always occur even rapidly. In still other cases, lungs and heart may both fail, the failure of neither being the exclusive cause of death.

Without designing or desiring to classify the causes of sudden death as cardiac, or pulmonary, or cardio-pulmonary, as observed by the obstetrician, I shall present the chief immediate causes of sudden death.

1. *Death from Mental Emotion.*—The fact that syncope may be caused by a strong mental impression, as fear, anger, joy, or sorrow, is familiar to the profession as well as to the public. A reasonable supposition is that in such cases the impression upon the brain is first reflected to the bulb, then probably through the pneumogastric nerves the bulb itself arrests the action of the heart, and hence the sudden paleness, the cerebral anæmia, and the syncope.[1] Wundt, adopting Kant's classification of emotions into sthenic and asthenic,[2] says that the former kill by apoplexy, and the latter by cardiac paralysis, or rather by the interruption of cardiac function which energetic and persistent excitement of the inhibitory nerves of the heart causes.

Several examples of sudden death from great joy are mentioned by Tuke in his well-known work,[3] and Montaigne has recorded[4] one of the most striking instances in which this was caused by profound sorrow. The familiar lines uttered by Malcolm in "Macbeth" show that the great master of tragic poetry recognized the truth that deep grief might cause fatal syncope:

> "the grief that does not speak
> Whispers the o'er-fraught heart, and bids it break."[1]

The greater nervous susceptibility of woman than of man, and its notable increase during pregnancy, would explain the special liability she would then have to be injuriously affected by a profound emotion, whether of pain or of pleasure. It[2] has sometimes happened that a premature labor has been thus caused, and in rare cases this labor been soon followed by death. But such untoward results are probably, as a rule, only consequent upon powerfully depressing emotions, or those which by Kant were called asthenic, such as great sorrow, grief, or fear, suddenly occurring. In case death follows this premature labor, it may be explained as caused by exhaustion, or the immediate cause may be hemorrhage from uterine atony, this atony itself being the result of the prostrate condition of the system.

Chevallier has collected and narrated cases of sudden death occurring to puerperæ which he attributed to idiopathic

[1] Strauss. Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques. Tome trente-quatrième.

[2] Elements of Physiological Psychology.

[3] Illustrations of the Influence of the Mind in Health and Disease.

[4] The story, as told by Montaigne in his Essays, is the following: "In the war that Ferdinand made upon the widow of King John of Hungary, about Buda, a man-at-arms was particularly taken notice of by everyone for his singular gallant behavior in a certain encounter, and, unknown, highly commended, and lamented, being left dead upon the place; but by none so much as by Raisciac, a German lord, who was so infinitely enamored of so rare a valor. The body being brought off, and the count, with the common curiosity coming to view it, the armor was no sooner taken off but he immediately knew him to be his own son, a thing that added a second blow to the compassion of all the beholders; only he, without uttering a word, or turning away his eyes from the woeful object, stood fixedly contemplating the body of his son, till the vehemency of sorrow, having overcome his vital spirits, made him sink down stone-dead to the ground."

[1] The same great poet has, in his "Julius Cæsar," represented Cæsar's death as not the consequence of injury inflicted upon his body, but of profound emotion:

> "For when the noble Cæsar saw him stab,
> Ingratitude, more strong than traitors' arms,
> Quite vanquished him: then burst his mighty heart."

Both these quotations attribute the failure of the heart to its rupture, and this accident is quite possible from emotional causes.

[2] Probably one of the earliest, if not the earliest, of all instances of premature labor caused by emotional disturbance, the labor being followed by immediate death, is that recorded in sacred history concerning the daughter-in-law of the high priest Eli. The great novelist and the great poet, whose pictures are true representations of reality, furnish similar examples. Thus, by way of illustration, in Scott's "Guy Mannering," Mrs. Bertram, suddenly learning the loss of her little boy, and thus subjected to violent sorrow, has a premature labor, and immediately dies. In Shakespeare's "Pericles, Prince of Tyre," Thaisa, the wife of Pericles, is far advanced in pregnancy, when in the passage from Pentapolis to Tyre a storm arises, threatening shipwreck, and the fear of this brings on labor whose end is quickly followed by death.

asphyxia. But, as remarked[1] by McClintock, "some very competent authorities look upon the mortal affection described by M. Chevallier as merely a form of syncope." Undoubtedly the latter term is the correct one. It is remarkable that several of the cases adduced were those in which death followed a strong emotion—in other words, they were instances of fatal emotive syncope. One of these, for example, taken from Morgagni, was that of a multipara who, after an easy labor, was delivered of a girl, her husband and she both being desirous of a boy; the sex of the child was imprudently told her, she was affected with such deep sorrow that her pulse became weak and her skin cold, and in a few hours she died; the autopsy presented no satisfactory cause of the fatal result.

McClintock quotes from Travers the following case: "A young lady, happily married, impressed probably by some unexpectedly fatal occurrence in the circle of her friends, entertained, from the commencement of her pregnancy, a morbid fear of death in childbirth, which, although unwarranted by any indication, became, from its continuance and increasing strength, a source of anxiety to one of her immediate and confidential relatives. She was attended by a skillful and experienced accoucheur, who was also her relation. He assured me that the labor was in all respects easy and safe, and that not a single unfavorable circumstance attended it. The child was still-born and imperfect. The mother died suddenly in six hours after delivery. Every region of the body was examined with care by an eminent anatomist, and presented the appearance of health."

Mordret has taken[2] from La Motte's "Observations" the case of a laborer's wife, who had to accept, though greatly dreading, the services of this celebrated accoucheur in a difficult parturition. LaMotte found an arm hanging from the vulva, and he readily performed version and delivered her of a dead child; the placenta too was delivered, but the woman was trembling, though she had no chill, and, half an hour after the labor, died without previous hemorrhage, pain, or any other appreciable accident. Mordret believes that the death was owing solely to fear.

2. *Death may result from Severe Suffering.*—A temporary syncope from violent pain has been often witnessed not only in females but in males, not only in adults but in children. It is not wonderful that the sufferings of childbirth, if very severe or protracted, should cause sudden death. Mordret remarks that an acute and continued pain is the most active enervant, and many times women die in labor or soon after, and the fatal result cannot be attributed to anything else than the excessive pains of a long and difficult delivery. The elder Ramsbotham and Travers had previously expressed a similar opinion.

3. *Death may be caused by Disease of the Heart.*—Cases of sudden death from fatty degeneration of the heart have been reported by Purefoy[1] and Jenks.[2] That of the former is as follows: The subject was thirty-six years old, and a primigravida. A short time before labor began, she complained of difficult breathing and præcordial impression, and these symptoms increased in severity with the progress of parturition; she died during the first stage. At the autopsy, the uterus and its contents were found in every respect normal; the os was dilated to the size of a crown piece; the presentation normal. The abdominal viscera were healthy; the lungs were in a state of recent congestion; the pericardium contained about two ounces of reddish-colored serum, whilst the heart was much enlarged, being in its greatest length about nine inches, and from four to five inches in breadth at its base. "This organ had undergone fatty degeneration to a considerable extent, with the usual softening of its muscular fibre, and, thus being unfitted for its office, had failed to fulfill its all-important function in the hour of need."

Franz[3] has reported the case of a multipara who died just after the delivery of the placenta, complaining of cardiac distress; the autopsy showed a fatty and dilated heart. Danyau in 1852 also reported a sudden death from the same cause, twenty days after labor.

Rupture of the heart has been in some instances the cause of sudden death of puerperæ. In a case reported[4] by Spiegelberg, death occurred in five minutes, three days after labor, and the autopsy showed rupture

[1] Dublin Journal of the Medical Sciences, 1855.

[2] Transactions of the American Medical Association, Vol. XXIX, Address in Obstetrics, "The Causes of Sudden Death of Puerperal Women." This address is a valuable contribution to the subject.

[3] Memorabilien, 1874.

[4] Monat. f. Geburt., XXVIII.

of the left ventricle as a consequence of acute myocarditis. In M'Nicoll's case,[1] a woman, two weeks after delivery followed by normal convalescence, while getting out of bed, exclaimed: "Oh! nurse, something has given way! I'm fainting." She died in twenty minutes, and upon post-mortem examination there was found an opening half an inch long in the walls of the right ventricle, which were very thin—fatty degeneration of the heart existed, although not to any great extent.

In connection with the first case reported, the views[2] of Coste may be stated. According to him, sudden death after delivery is due either to a hemorrhage, or to a thrombosis of the pulmonary artery, or to a myocarditis. As hemorrhage causes death more or less rapidly, and as, on the other hand, thrombosis of the pulmonary artery appears to be caused by a degeneration of the myocardium, we may conclude that sudden death after labor is almost always the result of myocarditis.

4. *Death may be caused by Rupture of the Aorta* —Henricius has reported[3] the case of a multipara, thirty-eight years of age, who, in the second stage of labor, the uterine contractions being good, and her general condition excellent, had suddenly occurring spasmodic contractions of the lower jaw and of the members for a few seconds, and then died. The forceps was used five minutes after the death of the mother, and a child delivered which was with difficulty resuscitated. The autopsy showed rupture of the aorta, which was attributed to increase of blood-tension caused by the violent uterine and abdominal contractions on the one hand, and on the other simultaneous reaction of the heart against this obstacle.

5. *Death may be caused by some one of the Accidents or Complications of Labor.*—Thus a patient may perish in eclampsia from acute asphyxia, though usually when asphyxia is the cause of death in this disease it is gradual, or it may be rapid, but rarely sudden. Inversion or rupture of the uterus may be immediately fatal in either case from hemorrhage or from shock, or probably in most cases from the two combined. Hemorrhage during labor, both when the placenta occupies its normal site and also when it is previous, and hemorrhage after labor, may be the cause of sudden death.

[2] De la Myocardite Puerperale comme cause la plus frequente de morts subites apres l'accouchement. Paris, 1876.

[3] Centralblatt für Gynäkologie, 1884.

6. *Pulmonary Thrombosis* has in several instances caused sudden death, but usually this accident does not occur in the earlier period of childbed, and it is generally preceded by phlegmasia alba dolens. The unhappy victim may have taken the erect or sitting position, after having been recumbent for days or weeks, or made other slight exertion, and death come suddenly almost as if from a thunderbolt.

But death may be caused by embolism just after labor, as a consequence of artificial thrombosis in a uterine vessel. Herman and Brown have reported the following case: An intra-uterine injection of a solution of perchloride of iron was used for post-partum hemorrhage, and the woman died, the death being attributed to an embolus from a thrombus in the uterine vein.[1]

7. *Death may be caused by the Entrance of Air into the Uterine Veins.*—Churchill, who almost alone among writers of works upon obstetrics very fully considers the subject of sudden death in the puerperal woman, states[2] that the absorption of air by the uterine veins was suggested by the younger Legallois in 1829, and by Ollivier in 1833, as being possibly the cause, at least of some, of the sudden deaths after delivery. Hervieux, after a full consideration of the subject, and the presentation of cases of death apparently from air embolism,[3] gives the following conclusions: 1. The incontestible reality of cases of sudden death from the presence of gas in the circulatory system of lying-in women. 2. The impossibility of attributing the presence of these gases to cadaveric cause—that is, to beginning putrefaction; the proved chemical identity of these gases with the gas of the blood, and the probability of their spontaneous development during life; the necessity of attentively watching lying-in women who have had severe uterine hemorrhage, and, although the introduction of air by the uterine veins has not been proved, the duty of the practitioner not to resort to intra-uterine injections except with the greatest reserve, and rigorously conforming to all the precepts of art.

Hervieux's scepticism as to the entrance of air into the uterine veins is not now at least the voice of the profession, for numerous cases have demonstrated the fact. Thus

[1] Obstetrical Journal of Great Britain and Ireland. January, 1880.

[2] Theory and Practice of Midwifery, sixth edition.

[3] Maladies Puerperales.

in the patient[1] of Olshausen, there was employed while she was in labor a uterine douche to hasten effacement of the cervix; she complained of pain, raised herself up in bed, gave some deep inspirations, and died in a minute. At the autopsy, made eight hours after death, bubbles of air were found in the cardiac vessels, in the uterine veins, and in the inferior vena cava. In Litzmann's case, four uterine douches were given with Mayer's pump, to induce premature labor; suddenly the woman became livid, and died in a few seconds. The post-mortem, made sixteen hours after death, showed bubbles of air in the uterine veins and in the ovarian and renal plexuses. Gunz has reported the case of a girl twenty years of age who was found dead in her room, having between her limbs an irrigator, the canula being in the vagina. She was found to be three months and a half pregnant, and the death was shown to have resulted from the entrance of air into the veins, the canula having penetrated the cervical canal. Spontaneous entrance of air is illustrated by the following case: A secundipara, twenty-five years of age, was after an easy labor delivered of her child while lying upon her side; she was then turned upon her back, gentle massage used, and the placenta was expelled. The face suddenly became livid, the respiration labored, the pulse weak; after vomiting a little mucus, and after slight convulsive movements, she became collapsed, and died. At the autopsy, the uterus was found as large as the head of a child, and its walls relaxed. In compressing the posterior wall and the fundus of the uterus at the place where the placenta had been attached, fine crepitation was heard; when the organ was thrown into water, a great number of small bubbles of air escaped. The parts of the uterus near the cervix did not appear to contain air, nor did the veins of the broad ligament, the ovarian veins, or the vena cava.

Another instance is the following: Cordwent has given[2] the history of a primipara, twenty-eight years old, who was delivered while standing of a living male child which fell to the floor, dragging the placenta and membranes with it. A "gurgling" was heard by the attendants, and the woman died almost immediately. At the post-mortem, air was found in the uterine wall at the fundus, in the coronary vein, and in the right heart.

Lauffs has collected[1] 43 cases of air entering the uterine veins. In 17, the accident was caused by injections into the birth-canal; 18 were spontaneous, and 8 resulted from the formation of gas in the uterus. 39 of the 43 were fatal, and the presence of air was proved by the autopsy in 31.

8. *Sudden Death may be caused by an Affection of the Respiratory Organs.*—Mordret quotes from Deviliers a case in which death occurred during labor five or six minutes after sudden aggravation of the symptoms of pulmonary congestion. At the autopsy, no other lesion than congestion of both lungs was found. La Motte has narrated a case in which death occurred suddenly after labor from a severe attack of asthma, and Depaul one in which the cause of the fatal result was pulmonary emphysema. Instances of puerperæ dying from pneumonia or from pleuro-pneumonia have been recorded, but in these cases the death was rapid rather than sudden. Pulmonary apoplexy, however, may cause sudden death.

There have been thus presented the chief causes of sudden death during or after labor. It must be added that, in a few instances in which such death occurred, it has been impossible even by a post-mortem examination to find the cause of the accident.

Merriman, under the head of "*Dystocia Syncopalis*," has given the following report of a case of sudden death in which probably the autopsy would have failed to show any organic lesion: "An accoucheur was once attending a woman in labor with her first child. Soon after it commenced, and during his absence, she fainted without any obvious cause. On his return, the circumstance was mentioned; but, as by this time she appeared perfectly recovered, no further notice was taken of it, and she was safely delivered without any other unusual symptom. On the third day after delivery, she took a dose of aperient medicine, and, while in the act of relieving herself, fell back and immediately expired. Probably no care would have prevented this unfortunate event. It was perhaps inexpedient to give the patient a purgative under such circumstances —a clyster would have been a more appropriate remedy, and at all events an erect posture should have been strictly forbidden."

[1] For these cases, see Braun on Sudden Death from the Entrance of Air into the Uterine Veins. Wien. med. Woch., 1883.

[1] Ueber Eintritt von Luft in die Venen der Gebärmutter bei und nach der Geburt. Bonn, 1885.

Charles has recently reported[1] a case in which the death was attributed by him to uræmic poisoning.

Spencer has reported[2] the case of an anæmic primigravida, who had eclampsia and premature labor, giving birth to twins; sudden death occurred, and the autopsy showed a large quantity of blood in the abdomen, no rupture of the uterus, but a gastric ulcer with rupture of an artery.

The late Dr. Charles D. Meigs in 1849 directed[3] professional attention to heart-clot as a cause of sudden death in the puerpera, claiming to have discovered that this accident most commonly depends "on the sudden coagulation of the blood that occupies for the time the right auricle of the heart, and, in some of the cases, even that which is in the ventricle and the pulmonary artery." His theory was that, in consequence of hemorrhage, the coagulability of the blood being increased, sudden exertion caused fainting, and in consequence thereof "the blood is likely to become concrete, if it but come to a stop in the auricle."

Playfair in 1871 reported[4] a case of sudden death after labor which he attributed to a thrombus in the right side of the heart and pulmonary arteries.

Haughton has reported[5] the case of a multipara who, ten days after normal labor, left the bed to evacuate the bowels; sudden syncope occurred, and in forty minutes she died. There was no post-mortem, and heart-clot was suggested as the probable cause of death.

Dr. Fordyce Barker states[6] that "observations have demonstrated that clots may form both in the pulmonary artery and in the right cavity of the heart, as a primary lesion."

Pathologists have not settled the question as to the formation of a primary thrombus in the right side of the heart and in the pulmonary arteries, some denying its occurrence.

The preventive treatment of this accident needs only brief consideration. Some of the cases here presented carry their own moral, plain to him who reads; in other instances, no human science and skill could have averted the fatal issue — death was inevitable.

[6] Puerperal Diseases.

It is important that the obstetrician should know not merely the physical, but also the mental, condition of his patient; knowing the latter, he may, by prudent speech and thoughtful suggestion and wise tact, defend her from perils to the body that come through the avenue of the mind. Coleridge said that he was the most successful physician in the treatment of nervous diseases who was most successful in inspiring hope. No matter how learned an obstetrician may be in a knowledge of the phenomena of labor, how great his experience, and how wise and skillful in the employment of artificial aids to labor, he makes his qualifications still greater if he knows how in all cases to inspire hope, dissipating gloomy forebodings, and sedulously guarding patients against all injurious mental influences, whether ignorant suggestions of meddlesome friends, or true statements made inappropriately in manner or time. If ever a woman needs to have both sympathies and antipathies respected, it is when enduring, or when she has just endured, the perils of childbirth.

So far as the actual management of labor is concerned, certain conditions liable to cause death demand artificial delivery. If the woman has been upon her side during the expulsion of the child, and then turns upon her back, this change should not be made without compression of the uterus through the abdominal wall during it. Intra-uterine injections must never be used unless the indication is unequivocal, and then preferably by an irrigator rather than by the ordinary syringe; so, too, injections of a solution of one of the iron salts are to be regarded as a last resort—they are rarely if ever required. Abrupt changes of position, and especially sitting up in the early days of the puerperium, even for evacuation of bladder or bowel, are to be avoided; such precaution is especially required if the woman was anæmic before her labor, or has had post-partum hemorrhage, or hemorrhage during the labor. Mental and physical rest is nature's instinct and nature's law for the puerpera.

MALARIAL COMPLICATIONS.[1]

BY SAMUEL WOLFE, M.D.,
SKIPPACK, PA.

The members of this society are all familiar with the onset and course of the malarial diseases which have during the last

[1] Read before the Montgomery County Medical Society, May 23, 1888.

eight years claimed so much of our time and attention: how about the beginning of the present decade, in a section in which for many years before they were practically unknown, there appeared suddenly over a widely distributed area, many cases of a typically regular form; how those affected and their friends were frightened by the violence of the onset, and hurried their physicians to the bedside; how after being controlled by quinia they recurred again and again; how the typical, regular form, soon degenerated into irregular forms in which it became very difficult to fix the period of intermission, or to decide whether there was an intermission or remission (rural practice not permitting the close observation of hospital or city practice); how, soon graver, more serious forms, which prostrated patients for days and weeks occurred; and how other diseases from the simplest cold to the most intense inflammations and the most lingering fevers were simulated or complicated by the manifestations of paludal poisoning.

You remember also, how we called our first cases ague, chills and fever, intermittent fever, or remittent fever; how we attempted to explain the nature of the cause, and the varieties owning it as their common origin; how our patrons soon applied the name of the cause to the disease, and how first we stood on high ground, yielding only enough to the seductive ease of the situation, to consent to group them under the head of malarial fevers; how we finally capitulated and thus gratified the vanity of the lay diagnosis by calling everything malaria, with the exception of unusually violent or depressing attacks which we called typhoid malaria, or if unusually prolonged, typho-malarial fever.

Our patients too, soon overcame their tendency to become alarmed at the onset, and waited till the urgent symptoms had subsided, and then visited the office, generally saving us the trouble of a diagnosis by telling us, they had malaria. They soon became familiar with the old form of prescription which a rhymester has satirized thus:

> "Quinia sulphas, drachma six;
> Diluted acid with it mix;
> Aqua pura—that's a hit,
> Addentur quantam sufficit."
>
> "Misce et signa—English plain—
> A teaspoonful, and then again
> When three full hours have passed away
> And so continue night and day."

We were obliged to seek new forms for our prescriptions as well as new names for the disease, but as the term malaria, however contorted, disguised, or hidden, still made the groundwork of our nosology, so the drug quinia, however substituted, dissolved, coated or encapsuled, still was the bulwark of our therapeutics.

> "Let me quote again
> Whose anti-periodic powers
> Professors eulogize by hours,
> Anti-pyretic virtues too,
> Ascribe to it, and so I do."

Indeed, from August, 1880, up to the present day, whether in summer or winter, I have seldom made a round of visits, that did not require an anti-periodic prescription. So constantly have diseases occurred, due purely to miasmatic causes, or complicated with a periodical impress which experience has taught me will require an anti-periodic to eradicate.

Now in view of these statements, I should like to take the liberty to consider that our venerated fellow-member, and my very warm personal friend, Dr. Hiram Corson, in his article, "Quinine—its Use and Abuse," published in The Medical and Surgical Reporter of May 5, 1888, has been a trifle severe in some of his statements. Not only does he want us to be more sparing in the use of quinia, but also to restrict the use of the term malaria, and thus to wrest from us the sinecure which to a large extent we have attained against our will.

The term, as a name for a class of diseases of which it is only the cause, as Dr. Corson says, objectionable as it is, is hardly as much so to my mind as the term typho-malarial fever. This appellation, I am certain, is frequently applied to remittents or irregular intermittents. If it has any proper place, it is to designate those cases in which the malarial and typhoid fever poisons are acting simultaneously on the same system. Why not call these cases of typhoid fever, and admit the malarial fever, whatever its form may be, as a complication just as we admit the existence of other complications, without in each instance, coining a name. It only falls short of the term typhoid pneumonia, so much used, in being needless, the latter, however, being more misleading, in tending to convey the idea that a disease (typhoid fever) is present, when it is not. It might of course be well urged that the greatest mistake lies in applying the term typhoid to the specific disease, which is better designated as enteric fever, but long usage, and the accepted understanding of it, will still plead for the term.

During the long period in which malarial fevers have been prevailing, the great majority of individuals have been in one or another way affected, and in many cases a decided cachexia has been established. We are not therefore without warrant, in many cases coming to us in which some other disease is undoubtedly present, in also recognizing a malarial complication, and trying to do, what Dr. Corson sarcastically calls, "getting it out of the system." Indeed it has very frequently been my experience that so soon as the patient has been "cinchonized," not only has the complication disappeared but the disease also, a result it would have been in many cases very irrational to expect had not the entire trouble been of malarial origin.

A few months ago, I was called to an unmarried woman, aged eighty-five, who for three or four days had been aphasic. The onset had been tolerably sudden. The patient could seldom get beyond a few words in framing a sentence. There were no other paralytic symptoms, except possibly a little distortion of the face. No fever, appetite fairly good. For about ten days I visited her at intervals of a few days, having used iodide of potassium, ergot, strychnia, and a blister to the mastoid process. The aphasic condition had remained about the same. In the course of my attendance, I gathered from her nurse that there was possibly the slightest tendency to better control of words in the evening. I gave her four grains of quinia sulph. every four hours for two days, and the trouble had disappeared with the exception of an occasional hesitancy in getting a word. She took Fowler's solution in three minim doses thrice daily for several weeks, and her condition is still as good as it was immediately after the use of the quinia. She can converse well, and complains of nothing but the debility incident to her age, and a sore pressure point immediately below the right ear.

About six years ago, I attended a man eighty-one years of age, who had had repeated attacks of intermittent, when one day he suddenly fell unconscious, after which he lay with blowing respiration and other usual signs of apoplexy for about six hours, when he slowly revived, and next day was sitting in his chair, chewing his tobacco, a picture of perfect senile contentment, rational, and apparently well. Next day he had a repetition of the same apoplectic signs, from which he again similarly recovered. He was brought under the influence of quinia, and had no recurrence.

An unmarried woman of fifty, a kitchen servant of mild and equable disposition, who had previously suffered from several attacks of "malaria," became possessed with the delusion that the members of the household and others were conspiring to kill her; could not be reasoned out of it; was in such a condition that if a commission in lunacy had at that time visited her, she would undoubtedly have been recommended to go under the care of the State. A slight evening remission was noticed, which was taken advantage of to administer full doses of quinia. In less than a week her insanity was gone, and has not returned, some five or six years having now elapsed, in which she has several times had intermittent fever.

Illustrative cases might be multiplied, and could doubtless be supplied by every physician in the county, but enough has been said to show what errors in diagnosis and treatment may occur, if we underestimate the importance of this fruitful source of disease; if we do not recognize the chronic systemic derangements to which not only its open and active attacks, but also its insidious and stealthy presence, may lead.

The initial symptoms of an attack—the chill, the headache, the short but intense fever, the aching pains, the vomiting and general depression all point to the nervous system, as being the portion of the organism more especially impressed by the cause of the disease, whatever its nature may be. The disturbance in nutrition, neuralgic pains, and general depression of the powers of the nervous system, all indicate that in the interference with its functions is established that state recognized as a cachexia. In permanent changes here lies probably the cause of the periodic impress which is given to all diseases, attacking an individual who has suffered repeated attacks of some one or of different forms of miasmatic disease; an impress which Dr. Maclean has conclusively shown to exist, and which he claims never wholly disappears.

It is, however, worth while to consider in this connection, that the original cause of the disease may continue to exist, and that while we acquire an immunity from the disease to such an extent that no active symptoms manifest themselves until the system becomes affected by another disturbing agent, then, when the resisting powers are sufficiently weakened, an outbreak may occur. This hypothesis would seem to be fortified by the fact that in the treatment of diseases under such circumstances, quinia

and other anti-periodics seem to exercise an unusually decided curative influence. And may it not be that from these very circumstances arises the great discrepancy in the opinions of various writers in regard to the value of quinia in certain diseases. As for myself, I believe that where quinia in doses beyond those required as an ordinary tonic does good, there is likely to be a malarial complication.

A CASE OF ACCIDENTAL CASTRATION.

BY JOEL CRAWFORD, M.D.,
YALE, VA.

On March 14, 1888, I was called at night several miles away in the country to arrest hemorrhage in a case of traumatic injury to the scrotum of a lad. On my arrival, I learned that the lad, while in the act of ascending a ladder, had been precipitated to the ground, and his scrotum, coming in contact with a stake which was driven into the ground near the foot of the ladder, was lacerated to the extent of about one inch and a half, the tear beginning at a point at the lower part of the raphe and extending obliquely upward and to the right over the right testicle, completely severing the excretory duct and other structures of the spermatic cord. The testicle was attached to the urethral portion of the cord only by a small filament of the tunica vaginalis. The septum of the scrotum had a small punctured wound in it, through which protruded a mass of apparently organized matter, which I at first mistook for the left testicle; but which I afterward learned, to my great pleasure, was composed principally of soot, salt, etc., which had been used locally for the purpose of forming a clot. The most singular feature about it was that a filament, extending a short distance through the punctured wound, similar to that attached to the right testis, was attached to this clotted mass, simulating a contused and lacerated testicle. As there was marked swelling and contusion of the parts, the left testis was not ascertained to be in situ and uninjured until the cavities were cleansed of the various débris, domestic styptics, clots, etc. The hemorrhage was readily checked, the edges of the wound were approximated and kept in position by sutures and adhesive plaster, and an antiseptic dressing soon brought about union by the first intention.

NEURALGIA.

BY BYRON F. DAWSON, M.D.,
KEWANNA, IND.

A case of neuralgia of great severity, suddenly shifting from one seat to another and yielding under prompt and vigorous treatment, occurred recently in my practice, and I think it is worth reporting.

The subject was a man, forty-three years old, a brick-maker, formerly an ex-soldier, married, addicted to the use of tea, coffee, whiskey, and tobacco, both chewing and smoking (a good neuralgic subject), though he has drunk little for several months. His father was an habitual drunkard.

March 26, 1888, he called at my office in an interval between the paroxysms of an attack of angina pectoris. For several months he had had irregular attacks of a very distressing præcordial pain, lasting from a few seconds to a minute or more, with a feeling of constriction about the chest, the pain shooting upward to the left shoulder and down the left arm, the uneasiness in the chest often continuing for several days. His occupation requires that a great deal of fuel shall be provided for summer work, and this he did largely alone during the winter, thus exposing himself to the severity of the elements. Once or twice while hauling wood, paroxysms came on and he had to drop his wood and catch hold of the wagon to support himself. In fact he presented all the characteristic symptoms of an attack of neuralgia of the heart. Careful inquiry elicited no family history of angina pectoris. He gave a history of repeated attacks of rheumatism, but on examination no cardiac lesions were found, though the valvular sounds were more feeble than normal; the pulse rate was 56, and feeble. He was of constipated habit. I gave my diagnosis and informed him of the danger of a continuation of his then present habits. He was ordered to abstain from the use of tea, coffee, whiskey, and tobacco. The following was given:

℞ Ext. Belladonnæ fld.
Ext. Digitalis fld. . . . . āā f℥ ss.
Ex. Nucis Vomicæ fld. . . . . f℥ i.
Glycerini . . . . . f℥ i.
Aquæ . . . . . q.s. ad. f℥ iv.
M.S.—Teaspoonful before eating.

He was also directed to take ten drops of Fowler's solution, well diluted, after eating.

Forty-eight hours later I was sent for to see the same patient at his home in the country. As regards the chest trouble

I found great improvement. He said he felt no pain there, and that he could throw his shoulders back and take a full breath, something he had not been able to do for months. At this time I found him sitting in a large rocking-chair, in great pain and scarcely able to stand or lie, and he slept none during the preceding night. Soon after beginning treatment as above the chest pain moderated, then a lumbago began, and soon there followed the ordinary symptoms of a well-marked double sciatica. Pain was produced by pressure behind the great trochanter, in the popliteal space, and at other points lower down in the course of the nerve; none by pressure over the kidneys. There were the distinct paroxysms of intense pain, and the dull ache in the intervals. The pulse was about normal, at 70; temperature, 99°. No family history of sciatica.

The patient was ordered to bed, and directed to use morphine (1-6 gr.) every two hours until relieved of pain, then as required; and four grains of potassium iodide and four minims of fluid extract of gelsemium in water every two hours, and a blister over each sciatic nerve. The former treatment was discontinued, except the Fowler's solution. Owing to either a misunderstanding or fear the morphine was not given, and he suffered greatly until four o'clock the following morning, when vesication began; relief was almost immediate, and the patient then had some refreshing sleep. The blisters were afterward renewed once. From that time convalescence was established, and five days later he came to town to an election, and in another week discontinued all treatment saying he "felt as good as ever." Since then he has been in his ordinary health, with no symptoms of either angina pectoris or sciatica.

In regard to the treatment of neuralgia in general—not specific—most standard authors advise the use of quinine and morphine, or with the addition of atropine, continued as circumstances require. Such treatment is undoubtedly successful as regards the neuralgia in most cases, but the danger of establishing a morphine habit is so great as to deter most physicians from the long continuance of such treatment. Iodide of potassium is recommended and used largely because of its power to cause absorption of exudates in or around the nerves, producing neuralgia by pressure. It is a safe remedy to use, as are also the various preparations of iron. Bartholow says of arsenic that it is "one of the most powerful of the so-called nerve-tonics." These various agents as forms of constitutional treatment in chronic neuralgia have all proven useful in my hands.

As an anodyne I have found a very satisfactory substitute for morphine in a compound recommended by various English authorities, but not by any of the American writers whose works I have examined, namely, fluid extract of belladonna and glycerine, equal parts, used locally; and certainly there is little danger of acquiring a "habit" in the use of this compound.

An admirable feature about this combination is that a powerful anodyne is kept constantly in solution in close proximity to the painful part by a vehicle that renders the skin soft and susceptible to the influence of such agents. This is a desirable substitute for the hypodermic injection of atropine which authorities recommend, for reasons that are evident, since it places the same narcotic agent in the same affected region under circumstances favorable for its absorption. Probably a solution of atropine in glycerine and alcohol, or the oleate of atropine, would prove as beneficial and at the same time be more cleanly, but I have not yet made the experiment.

The use of the fluid extract of belladonna in this manner without quinine has given me good results in cases of facial, dental, cervico-brachial, and intercostal forms of neuralgia. In gout it has proven useful, but in some cases the glycerine is objectionable and another vehicle must be chosen. Of course while this agent is being employed, constitutional treatment should not be neglected.

THE ARREST OF HEMORRHAGE FROM WOUNDS OF THE PALM OF THE HAND.

BY R. J. LEVIS, M.D.,
PHILADELPHIA.

My experience with hemorrhage from wounds of the palmar arches is that it is usually controllable by maintaining extreme elevation of the hand. This is most thoroughly effected, and with the least discomfort to the patient, by vertical suspension of the limb, the attachment being made along the palmar and dorsal surfaces of the forearm by adhesive strips, after the ordinary manner of making extension in the treatment of fractures. A cord from the adhesive straps may be fastened to the top of a bedpost or other convenient elevated point.

If posture alone should not arrest the

hemorrhage, the most effective compression can be made by placing in the palm of the hand an india-rubber ball, or a ball solidly made of cotton wadding, and on this the fingers and thumb should be closed and bound tightly with a roller bandage.

Using these expedients I have never been obliged to ligate arterial trunks for the arrest of hemorrhage from the palm of the hand.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, June 13, 1888.

The President, J. Solis-Cohen, M.D., in the chair.

Dr. William H. Parish read a paper on

Delivery Before the Seventh Month.

In the management of delivery prior to the seventh lunar month, the welfare of the mother is alone considered. The non-viability of the embryo or fœtus removes it beyond consideration. It is true that the question as to whether the threatened abortion or miscarriage is inevitable or not will frequently arise, and will challenge our most anxious study, for upon the continuance of the pregnancy hangs the life of the intra-uterine being if it is still living. It is my purpose, however, in this brief communication to discuss the management of only the inevitable deliveries prior to the viability of the offspring, and not to treat in extenso of any other part of the general topic of abortion or miscarriage.

The impossibility of ascertaining the number of abortions occurring in any large community has been generally recognized, so that the conclusions based upon figures given as to the proportional ratio of the number of deliveries of non-viable children compared with labors after the seventh month are unreliable. It is my belief, also, that the mortality following abortion or miscarriage cannot at present be arrived at even to an approximate degree. The desire to conceal the cause of death either because of the illegitimacy of the pregnancy, or because of criminal interference, or because of the known tendency of the gossiping, to ascribe all such deliveries, especially if fatal, to criminal interference, leads to the writing of misleading certificates. Some of the deaths ascribed to septicæmia, or pyæmia, or typhoid fever, etc., are deaths following abortions or miscarriages. Treatment must be based, however, not only upon the actual risk of a fatal result to the mother, but also upon a full appreciation of the fact that improperly-managed deliveries of non-viable offsprings entail upon the woman a number of serious conditions. Subinvolution of the uterus and of all the structures functionally associated or closely related by position is of frequent occurrence. Septic endometritis with septic endosalpingitis, ovaritis, and localized peritonitis, adhesions, crippled ovaries imprisoned, it may be, in lymph deposits, fixed and occluded tubes, permanently-damaged endometrium, acute uterine flexions and prolapse, and septic blood infection with impaired nutrition and nerve exhaustion—such are, in addition to a fatal termination, some of the results to be guarded against by judicious treatment. Again, many cases of acquired sterility are traceable to abortions or miscarriages, and extra-uterine pregnancy, known now to be of greater frequency than was formerly supposed, may be doubtless, in many instances traceable to tubes damaged by abortions.

He, then, who bases his treatment only upon the desire to save his patient from death, has not grasped the full indications of his case. To prevent death from hemorrhage and from intense blood poisoning is certainly his duty, but not his whole duty. His whole duty rests upon the indication of restoring the woman to the conditions of health both locally and generally, so that the various structures, especially of the pelvis, may be uninjured, and the various functions, especially of the sexual and related organs, may be performed with physiological ease and safety. Delivery during the early weeks of pregnancy is attended with a minimum of risk to life, yet subinvolution, often with endometritis and endosalpingitis, frequently follows such an abortion. About the third month begins the actual danger of death from hemorrhage and septicæmia, and this danger increases as the period of pregnancy at which delivery occurs advances up to the time when viability of the child begins and the phenomena of labor at full time more or less pertain. It should be borne in mind that crippling of the functional sexual capacity of the woman is liable to result whatever the period of non-viable delivery.

The treatment of such a delivery is divisible into the expectant and the active plans. The chief difference between these two plans consists, on the one hand, in securing artificially the emptying of the uterus if nature

does not effect this promptly, while on the other hand, such interference is strictly avoided, at least until symptoms determine danger to the patient. During the early weeks, there not arising practically any danger of loss of life, the plan of non-interference is not departed from by its advocates, and is adopted by not a few of those who resort to the more active treatment in the more advanced deliveries.

In early abortions, say prior to the end of the second month, in addition to rest for eight or ten days in bed or on the lounge, I have practised during late years antiseptic cleansing of the uterine cavity by means of one injection of a corrosive sublimate solution 1 to 4000; after the escape of the ovum I resort to only one injection and always use a return-tube catheter. I have not thought it necessary to resort to the curette prior to the second month, except when by reason of instrumental interference septic infection is especially liable. During the third month, in addition to the antiseptic intrauterine injection, I use a smooth wire curette, preferably immediately after the escape of the ovum, resorting at the same time to the injection. It is during and after the third month that dangerous hemorrhage may arise. If the patient is confined to the recumbent posture danger from this source, however, rarely occurs. If the bleeding appears, however, before the os is sufficiently dilated to admit of emptying the uterus, I tampon both the cervical canal and the upper vagina. For this purpose I prefer strips of baked cloth, because of the ease of introduction and of removal. Antiseptic syringing is resorted to both before the introduction and after the removal of the tampons. The tampon should not be resorted to as a routine treatment. Hemorrhage that is not controlled by the postural treatment and by cold applications, is the only indication for the tampon. After the os is dilated the best way of treating the hemorrhage is to empty the uterus and to inject into its cavity hot antiseptic water. In the absence of serious hemorrhage, the rule to avoid rupturing the membranes should be rigidly adhered to, inasmuch as an unbroken ovum tends to prevent or to check hemorrhage, and if the ovum is delivered with unbroken membranes, the placenta is most likely to be expelled in an intact condition. If the membranes have been broken, the embryo or fœtus usually escapes from the uterus, while the placenta and membranes remain within the uterus and are probably adherent to it. Suppose the embryo or fœtus has escaped, then, as is well known, the placenta and membranes will usually be expelled within twenty-fours, yet in a large proportion of cases they will remain within the uterus for days, weeks, or months. Does the continuance of the placenta within the uterus for even a few days at a non-viable period of pregnancy bring dangers to the patient? The answer to this must be absolutely in the affirmative. Such danger is a very considerable one to life from both hemorhage and septic infection. And even should the patient escape with her life, I do not believe that anyone ever escapes without serious injury to the child-bearing apparatus. Under such circumstance arise conditions which are likely to produce sterility or to determine subsequent abortions. Such patients suffer, it may be throughout their sexually active lives, with disturbances of the functions of the vagina, uterus, tubes, ovaries, bladder, and rectum with varying degrees of other local and constitutional suffering.

Septic changes of the products of conception under such favorable conditions of warmth, moisture, and contact of atmospheric air are developed so rapidly, that although absorption is probably not so rapid as at or near the full period of gestation, no one can say how soon the process of septic infection begins. The incipiency of such blood-poisoning is not heralded by any definite symptom. Even the rise of temperature, as shown by the thermometer, is not fully reliable unless observed every hour or two; and to wait until hemorrhage, or a rapid pulse, or a chill, or decidedly high temperature supervenes, will prove in not a few instances to be waiting until a fatal result is inevitable. Or should the uterus have emptied itself within a few days without evidence of danger of death, still in the great majority of such cases I believe that grave, and it may be permanent local damage will have resulted. We are told to let the placenta remain until there are evidences of danger and then to remove it. Wherein is benefit to be derived from such a rule of practice? Is it not wiser to take due precautions against fire than passively to await the development of flames within the building? An abortion or a miscarriage is a non-physiological accident, it is unnatural and pathological. There is no weight then in the argument that artificial removal of the placenta is unnatural and unphysiological and hence should not be resorted to. Its retention brings to the woman her greatest danger both as to life and to future

usefulness. A uterus promptly and rightly emptied, uninjured by traumatism and rendered aseptic, becomes a source of comparatively little, if any, danger.

As in labor after the child has become viable, so in abortions or miscarriages ergot is of great service after the uterus is empty. It then encourages involution, checks excessive lochial flow, expels clots, and lessens septic absorption. Before the uterus is empty this drug is seldom of more than limited value, and often is productive of actual harm.

When the hemorrhage is considerable and the ovum is intact, its administration will aid in controlling the loss of blood, but even here the tampon is usually sufficient. I believe that I have repeatedly seen the use of ergot retard the completion of the delivery by determining an undilatable condition of the cervix. Such belief has been strengthened by finding that under such circumstances the administration of an opiate hastens the delivery by relaxing a cervix that has been rendered rigid by ergot. In incomplete miscarriage, there is nothing more uncertain than the action of ergot. After its use the uterus may not empty itself for days or weeks, while the cervix closes so as not only to prevent the escape of the placenta, but also to prevent easy artificial extraction.

If you decide upon emptying the uterus, what is the best method of doing so? Prior to the third month the small size of the cervical canal renders the introduction of the finger difficult, and the curette is here sufficiently efficient, either before or after the escape of the ovum. The thickened decidua may then be readily removed with this instrument.

After the third month we have chiefly the placenta to deal with, and here the introduced finger is safer, more efficient, and more reliable than any curette. The finger more thoroughly and more certainly removes all the products of conception, and tells the presence or absence of such complications as polypi, fibromata, etc. When reliance is placed solely on the curette, the uterus may be supposed empty when it is not; fragments of placenta and of membrane, or even the entire placenta may be left, with extreme risk to the patient.

If one is present at the time of the escape of the embryo, and the placenta remains, he should at once, while the os is dilated, introduce his finger into the uterus, and while depressing and steadying the uterus with the other hand over the abdominal wall, dissect off *en masse* and completely the secundines, and remove them. To effect this it may be necessary to give an anæsthetic. After emptying the uterus it should be at once syringed with a hot corrosive sublimate solution.

There will be, in all probability, no indication for a repetition of the intrauterine injection, though daily intra-vaginal antiseptic syringing for eight or ten days has been my practice. If the case is not seen until several hours have elapsed and the placenta is still within the uterus, and ergot has not been administered, the os will be sufficiently dilatable to admit of an immediate resort to the prompt treatment. If at that time the cervix has already contracted because of ergot, the suspension of the ergot and the administration of an opiate, with non-interference of a few hours, will secure a dilatation of the os to such an extent as to permit the emptying of the uterus with the finger. If a number of days or weeks, or months, have elapsed and the symptoms indicate an incomplete emptying of the uterus, and the cervical canal is closely contracted, it will be better to dilate either with laminaria tents or with graduated bougies and to introduce the finger, than to rely upon any form of curette. After grave septic poisoning has occurred, a cervical canal that has been previously contracted undergoes a relaxation, and the placenta becomes detached or is so loosely adherent that its removal with the finger is usually a very simple procedure, and is, according to even the expectant practitioner, urgently demanded; but, immediately following removal of the placenta under such circumstances, evidences of more intense poisoning are frequently observed, and in many such cases a fatal termination eventuates.

There is but one form of curette that should ever be used for the removal of any of the products of conception. The perfectly dull wire curette is the only safe one. Every form of the sharp-edged instrument should be absolutely avoided. Simon's scoop is a dangerous instrument in the hands of the most careful. Much of the opposition to the curette is based upon the use of that or other cutting instrument. Even with the dull wire due caution must be used not to injure the uterus. A softened womb may be penetrated by even a dull instrument. My preference for the finger over the curette is based, however, rather upon the uncertainty as to the efficient working of the dull curette than upon its dangers. It would seem scarcely necessary to caution any one

not to mistake the somewhat elevated and roughened placental site for portions of the placenta itself; but in one instance I saw such a mistake made by an inexperienced gentleman who made active efforts with Simon's scoop until the uterine tissue was extensively gouged into by that dangerous instrument. Experienced men have left large masses of placenta—in fact, the fœtus and its placenta both—*in utero* after the cavity has been curetted. The possibility of double pregnancy with separate placentæ must not be lost sight of. I have seen an instance in which the physician removed with his finger under anæsthesia one fœtus with its secundines, and left within the uterus unrecognized a second fœtus and its placenta until uterine contraction secured their expulsion.

I have not referred to the various complications of non-viable deliveries. They are numerous and may call for special additional measures, but the management of the delivery rests upon no peculiar principle. Criminal abortion brings with it greater dangers, but usually the management does not differ materially from that of the non criminal delivery. In the criminal variety septic infection may occur before the abortion or miscarriage has begun, and the expectant plan of treatment is attended with the greatest dangers. An injudicious introduction of the sound may engender a septic inflammation of the endometrium and determine a fatal result before any part of the ovum is expelled. Under such circumstances non-interference contributes to death.

In inevitable abortion I have repeatedly emptied the uterus by compressing the body between two or three fingers within the vagina and in front of the uterus, and the other hand over the abdomen. I have also secured, in a few instances, a prompt ending of an incomplete abortion or miscarriage by the injection of hot water into the uterine cavity, of course securing its ready outflow. The hot injection awakens active corporeal contractions with cervical relaxation, and, if the fluid is antiseptic, diminishes the danger of infection.

Dr. William Goodell, in opening the discussion, said: I take exception to but one point in this admirable study, and that is to the use of the dull curette. I have given up the use of the dull curette for several reasons. There is great danger of wounding the endometrium in its soft, thickened, and vulnerable state; then there is this very danger the speaker has mentioned, of mistaking the placental site for tissue that should be removed, and the further danger, which he also admits, of perforation. I am sure that I once penetrated the wall of the uterus with a sound, and without using any force—though, fortunately, I escaped an evil result. There is danger of wounding that portion of the uterine wall which is not at all implicated, if I may so express it; and especially, two or three days after the abortion, would this cause a liability to the creation of a fresh raw surface upon perfectly healthy tissue, with additional danger of infection.

I use two styles of forceps—one, a small catch-forceps, which will seize anything that projects, or still better, a small fenestrated polypus forceps, which can grasp any projecting mass, however small, and that only.

Dr. Regar: How can we tell that the uterus is completely cleaned out? The finger cannot always determine with certainty. How long are we to keep up examinations and attempts at cleansing?

Dr. J. B. Walker: May we not answer the preceding speaker by saying that as long as the os is patulous, the uterus contains something that needs removal; after removal, contraction will occur. That has been my experience in several cases. I would ask Dr. Parish whether the rule holds good in all cases?

Dr. H. A. Slocum: I rather fear to follow the advice given to permit the ovum to escape entire. I remember two cases which fortunately terminated favorably—but which gave me much anxiety—in which the escape of the ovum entire was followed by alarming hemorrhage. One of these was in a well-developed florid woman, who had a history of repeated miscarriages. When I was summoned she was bleeding slightly, and the labor-pains were strong and constant. With my finger in the vagina, I waited for the ovum to be expelled entire. It came with a gush of blood that blanched the ruddy face of the patient and left her pulseless. I was compelled to remove the pillows, elevate the foot of the bed, and, with finger and hand, endeavor to excite uterine contractions, after which, with hot water injections and other appropriate measures, the bleeding was controlled.

When a uterus is distended with its contents, and the placenta leaves its site, and the large mass is suddenly expelled, it seems to me that the sinuses will be left wide open, and the contractile vigor of the uterus will not suffice to close them.

I agree with the advice to remove the

placenta as soon as possible. I remember a case, however, in the practice of a distinguished practitioner, in which—for what reason I do not know—it was left for six weeks free in the cavity, becoming hard and leathery, and was then removed under anæsthesia. My only connection with the case was to give ether, so that I know nothing further of the circumstances than that the placenta remained for six weeks without giving rise to any bad symptoms.

Dr. W. E. Ashton: I would take exception to the speaker's low estimate of the value of ergot. While I will agree that it is contra-indicated, except with a tampon, yet if the tampon be introduced and ergot then administered, the effect will be much more prompt and sure, and the presence of the tampon will prevent anything like hour-glass contraction. After a complete abortion I should consider intra-uterine antiseptic irrigation uncalled for, and rather dangerous as tending to introduce air, and, therefore, germs, into a uterus which is otherwise in an aseptic condition.

Dr. Parish: In reference to the use of the dull wire curette, Dr. Goodell could not have heard my remarks, or I must have failed to express myself clearly. I do not use it except at one stage, that is the third month—never after the placenta has been formed. I prefer the finger for many reasons, as I stated. Even with the dull instrument there is some risk of injury, and the method is unreliable. Dr. Goodell and I accord perfectly, after the third month. Before the differentiation of the placenta, however, the smooth wire curette will detach and remove the deciduous membrane with no danger.

I have used forceps, though not exactly the same form as spoken of, but the objection is that we cannot be sure with any form of instrument whatever that the uterus is empty. The finger alone tells us that. It is not only a therapeutic but a diagnostic appliance. It must be very rare for the uterus to possess the power to expel the ovum unaided, and then fail to take care of itself. There must be some special morbid condition to which the hemorrhage is due. In the case narrated by Dr. Slocum, with its history of frequent miscarriages, I should have suspected a polypus.

I do combine the use of ergot with the tampon, should the latter be insufficient when the ovum is intact, especially if the ovum is intact to give a smooth mass on which to contract. Antiseptic injections are indicated after such a pathological process as a miscarriage. I doubt if the uterine cavity usually closes air-tight after such a process. Not infrequently there is a separation of the uterine from the fœtal layer of the placenta with adhesion of the uterine portion. This adherent maternal layer is liable to give rise to septic inflammation and general infection.

The patulous condition of the cervix is, to some extent, an evidence that the uterus is not empty, but the reverse does not hold good. It would be unsafe to conclude that everything had been expelled because the os was found to be contracted.

Hospital Notes.

TREATMENT OF POST PARTUM HEMORRHAGE AT THE PHILADELPHIA LYING-IN CHARITY.

BY CHARLES P. NOBLE, M.D.,
SENIOR ASSISTANT PHYSICIAN.

Hemorrhage, post partum, comes either from the vessels of the relaxed uterine body or from lacerations of the genital canal. The term post partum hemorrhage is usually employed to indicate hemorrhage from inertia uteri after delivery. Indeed, the influence of lacerations is often overlooked.

The indications in hemorrhage from laceration, post partum, are plain, even if their fulfillment is not always easy—bleeding should be arrested by suturing the tear. The laceration may be of the vestibule, vulva, perineum, vagina, or cervix. Rupture of the body of the uterus presents so many serious complications that the resulting hemorrhage is often relatively a trifling matter. This accident has not occurred among the cases in the Charity during my connection with the institution. Lacerations involving the bulb of the vestibule are very troublesome, but fortunately are rare. The venous oozing is often obstinate and controlled only by the insertion of numerous deep interrupted sutures, or the use of the continuous suture. The continuous gut suture finds one of its most useful applications in the immediate repair of tears in the genital canal, especially when hemorrhage is the chief indication for closure. By its use the operation of suturing is quickly performed. All lacerations of

the perineum, excepting very superficial ones, are immediately closed. Silver wire requires less subsequent attention than other suture material, but silk is often used with equally good results. If sepsis occurs, infection along the silk stitches is apt to cause pain and require their removal. For this reason I prefer silver wire or silk-worm gut. Profuse hemorrhage has occurred in a number of cases from tears in the pelvic floor. A few arteries have required torsion before placing the sutures. Lacerations along the anterior and lateral walls of the vagina are more common than is supposed. They are not found because they are not looked for. In only one case have sutures been employed. This was in a primipara, whose labor was completed before the arrival of the medical attendant. There was a bilateral laceration of the cervix, which extended, on the left side, the whole length of the vagina and involved the perineum. Dr. Wilson sutured the entire laceration with silver wire. This is also the only case in which immediate trachelorrhaphy has been done. The patient recovered, but suffered from sepsis during the puerperium. In the cases at the Charity, lacerations have by no means been limited to instrumental cases. Immediate trachelorrhaphy is not indicated except for the arrest of hemorrhage. Experience here and elsewhere has proved that cervical rents heal kindly if the puerperium is normal.

Post partum hemorrhage proper, is due to inertia of the uterus. It has occurred after long tedious labors, in which frequently the forceps were necessary to complete the delivery. In ordinary cases, delivery of the placenta by the Credé method, which is followed more or less strictly by the various members of the staff, together with the subsequent administration of ergot, has been sufficient to insure permanent contraction and retraction of the uterus. The binder is always used, but solely with the view of promoting the comfort of the patient. Its influence in causing or keeping up uterine contraction must be slight. It has seemed to me that etherization favors hemorrhage, since it has been necessary to push it to the surgical degree, on account of the struggles of the patient under partial anæsthesia. In this respect it differs from chloroform; for with chloroform, often the patient need not be made unconscious, or only at the height of the pains, and thus systemic relaxation is not induced. The fall of the pulse to or below the normal, and the continuance of contraction of the uterus for half an hour or longer, are considered reliable indications that danger is over. The practice of keeping the hand on the hypogastrium for half an hour after delivery, so that the condition of the uterus may be constantly known, is unquestionably of the greatest value in forestalling relaxation of the uterus. The fact that no case of terrific post-partum hemorrhage—so graphically described by writers, in which in a moment the bed and floor are deluged with a stream of blood, and in which the patient is suddenly brought to the brink of the grave—has occurred, I attribute to the method of conducting the delivery of the placenta, and the careful watching of the state of the uterus for some time afterward. While I would by no means question the occasional occurrence of these unfortunate cases when every prophylactic measure has been employed, because such have been reported by accurate observers, yet it must usually be due to a contraction suddenly emptying a large amount of blood, which has been slowly accumulating in a flaccid uterus. Kneading the uterus through the abdominal wall is the most generally applicable method of securing uterine contraction, and it has often succeeded in arresting moderate hemorrhage.

The hot water, intra-uterine douche (110°–115° F.), after kneading of the uterus has failed to secure contraction, has been most often employed, with the invariable result of arresting the hemorrhage. Indeed for post partum hemorrhage, as ordinarily encountered, this is the best remedy. Not only does the hot water stimulate the uterus to contract, but it acts as a general stimulant as well. The water should be as hot as can be borne by the patient, and should be disinfected by sublimate. The only objection to the method is that it requires some minutes to get the apparatus ready. In ordinary cases this does not signify, as the flow can be arrested or temporarily diminished by kneading the uterus. The chief advantages of the method are the certainty with which it arrests the bleeding, and the fact that it leaves the utero-vaginal canal free from clots and in an aseptic condition.[1]

The introduction of ice within the vagina or uterus has not been much employed. This method has the advantage of being immediately applicable; but, on the other

[1] The late Dr. A. H. Smith, for many years connected with this institution, was an ardent advocate of the use of hot water intra-uterine injections for the arrest of post partum hemorrhage.

hand, it has serious disadvantages. The cold from the ice acts as a systemic depressant, and is disagreeable to the patient. The operator in the hurry is apt to neglect to disinfect his hand. And the ice itself may prove a source of infection, as Prudden has shown that ice is full of bacteria. It would seem that this measure of treatment should be held in reserve to be used only after the failure of other methods, or in cases where nothing else is at hand.

The hand has been introduced within the uterus in a few cases. In these the hemorrhage usually came on before the expulsion of the placenta. After separating and removing the placenta and clots, the uterus was gently irritated by the hand, assisted by friction through the hypogastrium, until contraction occurred, when the hand was slowly withdrawn.

Vinegar has not been used. I should think the best way to use vinegar would be to add it to the hot water and inject it within the uterus.

No case has called for styptics, nor would their employment be considered justifiable at the Charity until all other measures had failed. I should decidedly prefer Churchill's compound tincture of iodine to a solution of iron.

Faradism, although a promising agent, has not been employed. It has the advantage of entailing no dangers on the patient, and will unquestionably be tried.

Spraying the bared abdomen with ether is highly recommended. It has none of the disadvantages of dashing cold water on the patient, and should certainly be used to the exclusion of that procedure.

Much may be done in the general management of these cases. In hospital with trained assistants the physician is not so apt to lose his head, as when alone or surrounded by a frightened family. A confident and reassuring manner goes far to bring order out of confusion. When syncope threatens the patient's head is lowered and brandy, whiskey, or ether administered hypodermically. Ergot is always apt to excite nausea, and especially so when given after profuse hemorrhage. Systemic depression induced by vomiting would tend to increase the inertia of the uterus. Hence ergotin or the fluid extract of ergot is administered hypodermically. Ergot is most useful in keeping up contraction and retraction of the uterus which has been already brought about by kneading or the use of the hot water douche. No death from hemorrhage has occurred in the practice of the Charity.

Foreign Correspondence.

LETTER FROM BERLIN.

At the last meeting of the Society for Mental and Nervous Diseases, of Berlin, Dr. Albert Moll made a report upon hypnotism, and exhibited many illustrative cases. In Germany not so much attention is given to this subject as in France. At the same meeting, Dr. Moll also described the different degrees of hypnotism, following the French Professors of Nancy. He lays special stress upon the following, viz.: That hypnotism is a psychical state, and that objective symptoms are not necessary. "Because the latter is not regarded sufficiently, many cases of real hypnotic state have been mistaken for simulation. Only through much experience and by studying minutely the whole impression, and not through one single symptom alone, can we recognize simulation." Among different subjects which Dr. Moll showed, one case in particular is interesting, viz.: a case of pruritus, which he has treated and healed by suggestion during hypnotic state.

I will not omit to call your attention to a work just published in Berlin entitled "Bibliographie des modernen Hypnotismus, von Max Dessoir." It contains a very careful collection of the names of all works which have been published upon hypnotism during recent years. Through this work, we learn that in America the French investigations have not proved unsuccessful, and that several articles upon hypnotism have already been given in your journal. I would recommend the above named book to every one who intends to occupy himself with hypnotism. The clear and methodical classification which is given in this work, considerably lessens the difficulties which occur to every one who must search the necessary literature for himself. M. Dessoir will continue this work and, after a certain time, he will give regularly a review upon all new works respecting this subject. He therefore begs that all new works upon this matter should immediately be sent to him (Max Dessoir, Berlin, Kœthenerstrasse 27).

Dr. Leopold Casper, one of our cleverest doctors for the surgical diseases of the urinary organs, has communicated to the Medical Society of Berlin a new treatment for hypertrophy of the prostate. After having given a short historical sketch of the different treatments of this disease, and having called attention especially to the method

of Dr. Newman of New York, Dr. Casper described his own new method of treating the same. It consists in the application of electrolysis. The first trials were made upon animals, in order to prove clearly whether this method was dangerous or not. After having seen that it was not dangerous, Dr. Casper began to try the treatment upon men, in the following manner: The patient is turned over on the side, the rectum is filled with three fluid ounces of a solution of a mercuric chloride (1–1000). The indifferent pole is the positive, a large plate of 400 grm. It is applied to the abdomen. The electrolysis-needle must be pricked into the prostate from the rectum, and that part of the needle which remains beyond the anus must be fixed on to the negative pole of a galvanic battery. By degrees twelve cells are added, and the current has to be closed five minutes. After this time the needle must be slightly withdrawn, to enable one to turn it in the same hole, but placing the end of the needle in another direction. This is to be repeated for the third time, and each time the current has to be closed for five minutes. The strength of the current is from 10 to 25 milliampères. These sittings are to be made, according to the state of the individual, up to as many as twenty times. Dr. Leopold Casper has treated four patients in this manner. Three times it has proved successful. Of these three cases two have been greatly benefited. At all events Dr. Casper has shown that the operation, carefully executed, is perfectly harmless. In the discussion a recognition was given to the praiseworthy idea of Dr. Casper for this new treatment of the hypertrophy of the prostate.

Induced through the favorable reports of American medical men, Dr. J. Rosenberg has, in a case of a very severe attack of biliary colic, used olive oil in large doses with success. The case in which this oil was employed was that of a woman who had been suffering from this disease for the last five years, and who until now has been treated in different ways, but without any success. The pain had become, during the last year, almost unbearable; she had such great difficulty of digestion, that the whole constitution became extremely weakened. Through the administration of twenty-six fluid ounces of the oil of olives, in five doses, 629 gall-stones passed per anum, the largest of which was one inch in length and ¾ inch in width. Her sufferings have become considerably lessened, and an almost perfect recovery has been the result of this treatment. ALBERT MOLL, M.D.

Berlin, May 25, 1888.

PERISCOPE.

Quinsy Treated with Cocaine.

At the meeting of the Clinical Society of London, May 11, 1888, Dr. de Havilland Hall read notes of three cases of acute parenchymatous tonsillitis, or quinsy, treated with cocaine. In the first case, a laborer, 28 years old, was admitted into the Westminster Hospital, September 28, 1887, suffering with quinsy. He had had two similar attacks in the last five years. On admission, he had been ill four days. The right tonsil and adjacent soft parts were enormously swollen, and he was unable to swallow without the greatest difficulty and pain. On the 30th, there was complete inability to swallow, but, after painting a twenty per cent. solution of cocaine freely over the whole of the fauces, the patient was able to swallow some bread and milk. The same night the left tonsil became affected, and the cocaine solution was applied again next day with an equally good effect, and the day following he was able to swallow bread and butter. No suppuration occurred. The patient left the hospital quite well, after being in one week instead of four and three weeks respectively, as on the two former occasions.

In the second case, a publican, 25 years old, was seen in consultation with Mr. Wright at Kennington, October 26, 1887. When seen, the patient's complexion was dusky; he was suffering with some dyspnœa and dysphagia. Both tonsils and the soft palate were greatly swollen, and were covered with a viscid secretion, but there was no false membrane. Pulse 120, feeble. Urine, specific gravity, 1030, loaded with albumin. The patient's condition was a most anxious one. The throat was swabbed out with a twenty per cent. solution of cocaine, and the application was repeated in ten minutes. Five minutes later, the patient was breathing more easily, and was able to swallow half a pint of egg, milk, and brandy. During the next two days, applications of cocaine were made night and morning, and one on the third day. The patient gradually improved, no suppuration occurred, and a week later the urine was free from albumin, and he was well.

In the third case, a porter, 39 years old, attended at the Throat Department of the Westminster Hospital, November 16, 1887, complaining of sore throat and inability to swallow for thirty-six hours. He was previously quite well. The left tonsil and adjacent parts were swollen, and there was a

yellow patch on the tonsil. Pulse 88, fair volume. Temperature 102.2°. The urine contained a trace of albumin. A twenty per cent. solution of cocaine was applied, and the patient was soon able to swallow half a pint of bread and milk. Four days later the patient had no difficulty in swallowing, and was practically well. In all three cases, as soon as the patients could swallow easily, tincture of the perchloride of iron, with or without quinine, was ordered.

Dr. de Havilland Hall pointed out that cocaine had a twofold action in these cases; it diminished the sensibility of the parts to which it was applied, and at the same time lessened the blood-supply, hence deglutition was much facilitated. He also thought that it checked suppuration. He advised the throat to be sprayed out with a solution of bicarbonate of sodium, ten grains to the ounce, before the cocaine was applied; by this means less cocaine was needed, as it appeared that cocaine acted more efficaciously in the presence of an alkali. Dr. Semon said he had seen cases in which cocaine had been too freely used. Patients obtained cocaine pastilles from the chemist and used them indiscriminately. A woman, suffering with asthma, with cough, coryza, etc., being ordered a ten per cent. solution, procured a twenty per cent. solution, which she used occasionally to the nostril for two years. One night, after so using it, she awoke from sleep feeling very ill, and with her heart's action very irregular. She recovered after a time, and had since then had a wholesome fear of cocaine. Another patient—a man—had severe poisonous symptoms from the use of only the sixth part of a grain. Dr. Semon was of opinion that some patients could not use it; on the other hand, he had seen a patient suffering with tonsillitis—who had had aphagia for twenty-four or thirty-six hours—become able to swallow with some comfort only ten minutes after an application of cocaine to the fauces. Dr. Hall, in reply, mentioned that last week he had applied a twenty per cent. solution of cocaine to the nostril of a young and strong man, who was very much affected by it, became faint, and had to lie down for nearly an hour before the effects passed off, although ether and other stimulants were given. He always applies the solution now with a brush, all the cases in which untoward symptoms had showed themselves having occurred when he used the spray. He remarked that peri-tonsillar inflammation seemed to take place in some cases when practically no tonsillar tissue was left. He thought that cocaine was of use only in parenchymatous tonsillitis; the same good results had not followed its use in follicular tonsillitis.—*British Med. Journal*, May 19, 1888.

Anomalous Scarlet Fever.

In the *Practitioner*, February, 1888, Dr. William Squire discusses anomalous scarlet fever, with special reference to the recent epidemic of scarlet fever in London, and to the epidemic of "suette miliaire," which prevailed in Poitou, France, in 1887. Anomalous rash, perspiration, and perhaps rheumatism, he says, seem to be most common in summer; bad throats, cough, and congestion of lung in the winter; diarrhœa and jaundice, the latter rare, are less associated with season; while constipation is more an accident of prolonged convalescence. Any sore throat in the autumn, or any affection of the tonsils, with spots or ulcers in the winter, is to be looked upon with suspicion. In the summer, persons with sore throats, adults especially, go out and neglect the febrile disturbance with which it commences until they see the redness extending from the neck or wrist where the collar or cuff has rubbed. With children in bed, he says, a limited patch of redness on the abdomen, back, or groin, instead of at the neck or wrist, is found. This irregular scarlet fever may at first pass under the names of *erythma fugax* or *multiforme*, and later extensions of the rash be called *lichen ruber*. In another form of scarlet fever rash, acuminate papillæ are seen, perhaps minutely vesicated at their apices. When perspiration accompanies the eruption, fine sudamina may occur. Petechiæ and spots of purpura have, not unfrequently, been seen. Sometimes the rash may appear as a mere suffusion of the surface so transient as to be overlooked in children with delicate skin; in older persons the skin may have a harsh or rough surface, which, with swelling of the neck, face, and eyelids has passed for erysipelas. With reference to the epidemic in London, he says:

"The first case was the son of a medical friend residing to the north-west of London, who was seen by me one summer with this accident during the eruptive stage; he had had a hot bath the evening before on the sudden ingress of suspicious symptoms. A younger brother, who was his companion at a day-school, now remained at home, and a few days after had similar symptoms, and though no hot bath was given, perspiration accompanied the eruptive period." Another instance fresh in his memory is that of two

tall well-grown lads, recently arrived in London, living in lodgings with their mother. One evening in May the elder, a medical student, felt suddenly ill; he perspired profusely in the night, and remained next day in bed with sore throat, fever, rash, and perspiration. The last symptom continued during a well-marked scarlatina eruption; small raised spots of epithelium and dried exudation were soon left on the face and chin, and sudamina formed on the chest amidst the scarlatina rash. The younger brother, attending a large day-school, was kept at home, and shortly after symptoms of scarlet fever began in him, also with perspiration.

Neither of these cases was of great severity, and no infection was spread from them, or there might have been a form of scarlatina of all degrees of severity propagated, with perspiration as one of the characteristics. Albuminuria was not found in any of the anomalous cases here described, though looked for, he says, carefully in all stages of the illness.

Perspirations with sudamina were frequent in the anomalous scarlet fever described in the November number of the *Archives générales de Médecine.* (See REPORTER, November 26, 1887, p. 713.) The name *rougéole* is there used merely because the first fatal cases among young children were so registered; reports from different localities agree that the attack is not like that of ordinary measles; it begins with vomiting, it lasts longer, it is a bad sort, very fatal even to those who have already had measles; the rash differs, it spreads uniformly, pearly spots are seen on the red surface when there has been much perspiration; there is after-peeling of the skin in flakes—a sufficient proof of scarlatina. The chief anomaly was profuse perspiration, this marked the fever accompanying the eruption; the next anomaly was a violent cough and some coryza before the rash, and swellings of the eyelids, but, as is noted, these symptoms preceded the rash by only one day, and not by three or four days as in measles, though bronchial râles in some cases were heard later; moreover, clear instances of short incubation are given with the pertinent question: "Is there a form of measles with only one day of incubation and one of invasion?" In the half year up to midsummer, in a population of 20,000, rather more than 2,000 cases occurred with 200 deaths; at first young children suffered most, some of these with the special sweating that became a marked feature in adults affected by the exanthema, and which soon got to be looked upon as a new form of "sweating sickness." Another anomaly was a pause in the evolution of the rash, sometimes a second interruption, with renewed fever and perspiration as the further eruption appeared; this was limited to the first week of the attack and to the worst cases. Instances of true relapse occurred in the first few weeks of convalescence; with renewed rash, the fever and perspiration recurred, sometimes with more severity than at first; relapses are mentioned as late as the second or third month. Headache and epistaxis were frequent; petechiæ often accompanied the rash; passive hemorrhages, if late in appearing, were not of bad augury. Convalescence was tedious, sometimes with a very slow pulse or with palpitation, and often lasted six weeks; constipation was common, and often œdema of the legs and feet; albuminuria was not detected, but seems not to have been searched for in any great number of cases nor at many intervals in any one case. Without precise records of such examination it is impossible to affirm that albuminuria was absent. In one case anuria lasted some hours with subsequent return of the normal secretion. The danger to life was greatest during the eruptive period, and death after the fifth day was rare. The disease was eminently contagious, the incubation short; in some districts only the rash was noticed, in others the perspirations were superadded, and these cases, mostly adults, would give rise to other attacks with rash only in infants. The eruption described is quite characteristic of scarlet fever; it appears on the second day; it is uniformly diffused on the body while yet scattered on the limbs or in bright spots on the back of the hands and feet; the sore throat shows smooth redness of tonsils and redness of the palate with brighter points visible; minute red points slightly raised are to be seen and felt on the skin, the redness was often very marked at the wrists; after perspirations traces of small miliary vesicles are found on the chin and cheeks; pearly spots are seen upon the redness of the chest, and on the wrist the sudamina sometimes coalesce; this is quite distinct from the after desquamation found in all the cases.

The value of the paper from which these facts are gathered is increased by an account of six similar epidemics—three of these are certainly associated with scarlet fever, as in that of 1863 described by Dr. Bordes, of Beauvais. In severe epidemics of this kind it is curious to see how popular ideas revert

to traditions both of small-pox and measles; in this epidemic of Poitou some of the fatal cases with hemorrhagic spots were called "black measles" in memory of the hemorrhagic small-pox of fifteen years before; just as in Sydenham's time fatal scarlet fever in England was called "confluent measles."

The Surgical Treatment of Malignant Growths.

At the meeting of the Massachusetts State Medical Society, June 13, 1888, a paper on the Surgical Treatment of Malignant Growths was read by Dr. Maurice H. Richardson, of Boston. Dr. Richardson's paper was based upon an analysis of all the cases of easily accessible tumors treated by excision in the Massachusetts General Hospital from November 1, 1877, when antiseptics began to be used there, to January 1, 1887. These probably included some growths not malignant, and to a certain degree the statistics are not accurate, but some justifiable inference can be drawn from them. It was intended to investigate the subsequent history of all the cases so far as possible. Of the 833 cases, 498 had been heard from; and of these 251 were living and 247 were dead. Dr. Richardson took issue with Dr. Hodges' recent statement that operation for cancer of the breast is exceptional or soon will be. From the tables he had compiled he was led to believe that early diagnosis and excision in malignant growths were advisable. Two prominent causes of failure were lack of thoroughness and insufficient attention to glandular infection. Operation for cure should not be done unless all the growth can be removed, but of course operations for mere palliation do not demand this condition. The best time is the earliest possible, and removal should be complete without reference to scar or mutilation. The infection of lymph-glands was almost a contra-indication for operation. The speaker would, in operating for mammary cancer, dissect out the axilla and remove all its fat. This method adds to the danger of the operation and impairs the mobility of the arm.

Dr. H. H. A. Beach, of Boston, said that the statistics, if somewhat disappointing at first sight, are a verification of the traditions and experience of the hospital surgeons in operations for the removal of malignant disease. The apparently slight increase in mortality in breast-cancer may be fairly accounted for by the fact that cases which were not considered appropriate ones for operation some years since, because of glandular infection, are now, with the aid of modern antisepsis, made less dangerous undertakings to the patient in so far as *septic* disease is concerned; but the mortality from a more rapid recurrence of the cancer is inevitably greater in many of the cases, from the fact that a majority of the patients report to the hospital too late to insure a radical removal of the disease.

A class of cases in which it is impossible to make a wide sweep into the healthy tissues, or one sufficient to insure a long immunity from recurrence, the relief from pain and hemorrhage resulting from the removal of a mass of disgusting disease, with strict antiseptic precautions to insure the patient from a worse set of symptoms through septic poisoning, justifies operations that otherwise should not be undertaken.

Many operations of this character are done in all large hospitals, where proper after-care and attention are practicable. Such cases show a rapid return of the disease, and so unfavorably impress statistics. They are none the less justifiable if they furnish a reasonable amount of relief. While it has been claimed by an eminent authority, on the one hand, that the time would come when cancer of the breast would not be operated upon, strong arguments are presented, on the other, in favor of its local character and of operations calculated to radically remove the disease by excision of the breast and clearing out the axilla.

Surgeons of large experience will readily recall cases in which to have followed the first dicta would have consigned their patients to a premature grave, in place of years of comfort and happiness. To have accepted the second would have put them in the position of attempting an anatomical impossibility: that of *completely* removing the glandular, lymphatic, and fatty structures of the axilla, excepting in the cadaver. Either of the tissues named may be infected by the disease, and the only excuse for clearing the axilla that can be reasonably offered is that it is in the usual line of the extension of the disease, and provides for the removal of a wider periphery of sound tissue from the centre of infection. This procedure may offer a longer immunity from recurrence, if done sufficiently early, the gland having been enlarged by irritation in place of infection, and time *may* prove it to be a cure, but for the present the question is yet undecided for want of sufficient evidence. —*Boston Med. and Surg. Journal*, June 28, 1888.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

RHEUMATIC PERIPHERAL NEURITIS.

The clinical symptoms and physical signs of an ordinary attack of acute articular rheumatism are almost as well known to intelligent laymen as to physicians; but there are phenomena occurring during, or subsequent to, an attack, which are not described in text-books on medicine, and are scarcely mentioned even in monographs on rheumatism. Such phenomena are paralysis and atrophy of muscles, anæsthesia in the course of peripheral nerves, and occasionally enlargement of the ends of bones. In a communication in the *Medical Chronicle*, June, 1888, DR. JUDSON S. BURY calls special attention to peripheral neuritis in acute rheumatism, and to the muscular atrophy which occurs in connection with affections of the joints. He does not lose sight of the fact that muscular atrophy has long been noticed as one of the accompaniments of other diseases of the joints, but, on the contrary, seeks to determine how far the element of joint disturbance, which is common to all the joint affections, may account for the atrophy, and if there are other factors at work in the rheumatism itself which are equally potent with the former in setting up muscle waste. His paper is a very complete one, containing an account of the history of eleven cases, and is illustrated with numerous wood-cuts, showing very clearly the appearances occasioned by the atrophy.

It is impossible, in the space we can spare, to do more than give a condensed statement of the conclusions of Dr. Bury's study. He believes that we continually meet in articular rheumatism with the muscular atrophy and paresis which are common to other joint affections; and that, while the sudden onset of these symptoms appears to be best explained by a reflex mechanism, by which an irritation from the joint is conveyed along sensory nerves to the cord and inhibits in some way the functional activity of the motor cells in the anterior horns, yet the progressive character and duration of the atrophy suggest organic changes, either central or peripheral. He regards the presence of increased tendon reactions, and sometimes of contractures, as indications that there may be changes, not only in the motor cells, but also in the terminations of the pyramidal tract, or in that network of nerve fibrillæ by which they are supposed to be connected with the ganglionic cells—changes which are probably organic.

One of the most common, as well as the most conspicuous, of the muscle atrophies, is that of the interossei of the hands. This Dr. Bury refers very plausibly to an ulnar neuritis, pointing out that in ulnar paralysis the index and middle fingers are less affected than the two inner fingers, because the outer two lumbricales are supplied by the median. He also thinks that rheumatism seems to attack especially the adductor pollicis and the abductor indicis. He finds confirmatory

evidence of neuritis in the frequency with which impaired cutaneous sensibility is met with in the ulnar nerve territory, along with thickening and tenderness over the trunk of the nerve itself. It must not be inferred that the ulnar is the only nerve affected, for there is good reason to believe that other nerves of the brachial plexus, as well as the branches of the lumbar and sacral plexuses, are also frequently attacked. He regards it as of great significance that these peripheral nerve symptoms may occur in a limb quite free from joint irritation, as, for example, during early convalescence from rheumatic fever.

Dr. Bury's conclusion, therefore, that there are justifiable, if not conclusive, grounds for believing in the existence of a rheumatic neuritis, seems moderate and well borne out by the facts; indeed, his whole paper bears evidence of having been the result of thorough study, and is rendered especially valuable to one desiring to follow up the subject by having a copious bibliography appended to it. Dr. Bury devotes no space to a consideration of prognosis or of treatment; but it will occur to the thoughtful physician to carefully watch, from the beginning, every case of rheumatism, if only for the purpose of giving the patient and his friends timely warning of the commencement of a muscle atrophy which may seriously impair his future usefulness. Another thought, which it is well to keep in mind, is that it may be possible, by the selection of a suitable climate, to prevent attacks of rheumatism, and so put the patient in the best possible condition to recover lost power, or, at least, to resist further increase of the atrophy.

IMPROVED CÆSAREAN SECTION.

In order to appreciate what has been done by the improved Cæsarean section, it is necessary to review the status of the classical Cæsarean section, and its substitutes, the Porro operation, and laparo-elytrotomy. The classical Cæsarean operation has been performed in America about one hundred and forty times, with a maternal mortality of sixty per cent., and a loss of fifty-eight per cent. of the children. In Great Britain the maternal mortality in one hundred and eighteen cases, collected by Hull, Radford, and Harris, was eighty-one per cent. Mayer, quoted by Schröder in 1874, gives the maternal mortality in Germany, in seven hundred and twelve cases, as fifty-three per cent.; in France, in three hundred and forty-four cases, as fifty-five per cent. Charpentier estimates the mortality at from fifty-four to sixty per cent. The results were especially bad in hospitals; all the cases operated upon in the Vienna Hospital, and in the Paris Maternité for nearly a century, had proved fatal. This mortality, though fearful to contemplate, is by no means surprising when all the circumstances are considered. The operation was usually done as a last resort, often after the failure of all other operative methods; the women were often in labor for days, with tissues bruised or lacerated from instrumental interference, perhaps already septic; the uterine suture was seldom employed, and the method of operating was often haphazard and utterly bad. The wonder is that so many recovered. Harris, in 1879, published the reports of twenty-seven timely operations, carefully done, in this country, with a saving of twenty mothers, and the delivery of twenty-two living children. This shows the possibilities of the classical section when carefully performed. Laparo-elytrotomy has been done twelve times: six mothers recovered, and eight children were delivered alive. The Porro operation, in one hundred and sixty-four cases, has saved scarcely more than forty per cent. of the mothers.

The steps of the improved Cæsarean section may be succinctly described as follows: 1. The usual preparations for abdominal section; 2. Emptying the bladder, shaving the pubes, and carefully disinfecting the abdomen, vagina, and external genitals; 3. Incision in the linea alba; 4. Incision in

the uterus, in the middle line, avoiding the inferior segment—the abdominal walls must be held firmly and closely against the uterus to prevent the entrance of blood or liquor amnii into the peritoneal cavity—; 5. Extraction of the fœtus, by the feet or head; 6. Eventration of the uterus, placing a sponge or napkin under it, stimulation of the uterus by friction—the abdominal walls must be held together to prevent the escape of the intestines while the uterus is covered by warm, wet, antiseptic napkins—; 7. Separation and removal of the placenta and membranes; 8. Irrigation of the uterus, if indicated, with sublimate solution, and introduction of an iodoform pencil; 9. Placing the sutures: (a), deep sero-muscular sutures, eight, ten or more, of silk or silver wire, avoiding the mucosa; (b), superficial, sero-serous Lembert, twenty or more of silk; 10. Toilet of the peritoneum, with sprinkling of iodoform along the uterine incision; 11. Suturing the abdominal wall; and the dressings usually employed after laparotomy; 12. Expectant after-treatment. The Müller modification, of long abdominal incision, uterine eventration before incision, with elastic ligature to the cervix, has been generally abandoned. Resection of the muscularis, as proposed by Sänger, has also been omitted. The elastic ligature may be necessary after extraction of the child and eventration of the uterus, while the sutures are being placed; or hemorrhage may be controlled by manual compression of the cervix, or by torsion of the uterus. Placenta previa Cæsaria is to be met by rapid incision, extraction of the fœtus, and separation of the placenta, or by torsion of the uterus and incision beyond the placental border, should the diagnosis be made before incision. Injections of ergotine are useful to insure uterine contraction. The most essential features are early operation, asepsis, and careful uterine suturing.

The improved Cæsarean section is commonly styled, especially in Germany, Sänger's operation. Aside from the disadvantages of personal nomenclature, it is more than questionable whether Sänger has claims to such a distinction. There is no question that the present interest in the improvement of the technique of this operation has been largely brought about by the writings and influence of Sänger, and for this he certainly deserves, and has received, great credit. But it can hardly be maintained that he has added anything new to the method, since the excision of the musculature has been abandoned, and the principle of the approximation of peritoneal surfaces had been recognized and employed in practice, and the double sero-serous suture had been used, before he published his book in 1882. Lungren, of Ohio, in 1875 and 1880, employed the suture so that the peritoneal surfaces are retained in contact until union takes place, and all danger of escape of fluids is averted; and Baker, of Indiana, brought his carbolized silk sutures out at a short distance from the incision through the peritoneal coat, so that when they were tied, they brought the peritoneal coats together first. Spencer Wells, in 1881, clearly proved the advantage, not alone of a sero-serous suture, but of deep muscular sutures as well. This applied to the removal of tumors from the non-pregnant uterus. But Kehrer, in 1881, used a double row of sutures, muscular and sero-serous, thirty-five in all. The deep sutures were passed through the mucosa, and not through the peritoneum. Sänger especially emphasized the necessity for a large number of sutures, particularly for the superficial row, and dwelt upon the danger of infection where the mucosa was included in the sutures. Moreover, were it established that some step in the operation was first suggested by Sänger, it would be contrary to all precedent to prefix his name to the operation, for it was first performed by Leopold in its various details, while Sänger's name appears as the eighth on the list.

The indications for the Cæsarean section

are either absolute or relative—absolute, where it is impossible to deliver a mutilated child by the natural passages—relative, where the pelvis is so contracted that the fœtus cannot be delivered at term without mutilation. All obstetricians are agreed upon the propriety of Cæsarean section where the indication is absolute, but they are by no means unanimous as to the criterion by which to estimate the indication. While it is generally stated that a diameter of one and a half inches in one direction and three inches in the other is absolutely necessary to extract even a mutilated child, yet Osborne extracted through a pelvis of eight-tenths of an inch, and Pajot has succeeded by his method of "repeated cephalotripsy without traction" with a conjugate of less than an inch and a half. Charpentier, who does not accept the relative indication, says, "for the majority of accoucheurs the indication is absolute, under one and one-half inches." Playfair, Barnes, and Galabin, who occupy the same attitude toward the operation, say the same. Tarnier considers the indication absolute at one and nine-tenths inches. Naegeli and Grenser consider two and five-tenths inches as the extreme limit for embryotomy. Cases in which the indication is relative should be divided into those in which section and those in which embryotomy is safest for the mother. Reliable statistics of embryotomy, suitable for comparison, are difficult to obtain, because most of the statistical tables were compiled before the antiseptic era, and better results could now be had. Maygrier reports thirty-two cases of cephalotripsy, true conjugate two and one-half inches, mortality forty per cent., twenty cases, true conjugate two and three-tenths inches, mortality fifty per cent. Jaggard, however, has collected three hundred and fifty-nine cases in the hands of expert operators, reported between 1871 and 1883, with a mortality of only five and fifty-seven hundredths per cent. He expresses the opinion that with pelves above six centimetres, cranioclasis, after Braun's method, properly performed, should give a mortality of zero. It must also be remembered that Van Huevel's forceps-saw and Hubert's transferator have given most excellent results. While it is by no means proved by reliable statistical evidence, it may be accepted that in pelves not exceeding two inches in the conjugate, embryotomy is more fatal than Cæsarean section, and it is generally stated, especially in Germany, that section is the safer under two and one-half inches. Some would raise the indication to three inches with a living child. The improved Cæsarean is now in fashion, and the tendency is decidedly toward widening the relative indication. The mother's wish, after a fair presentation of the facts, is the strongest indication. Where the dangers from section and embryotomy are about equal, the life of the child should be considered, perhaps also when the mother is suffering from mortal disease, as cancer. But bold is the operator who wilfully endangers the mother to save the child, for, as Cazeaux justly says, "the experience of centuries proves, supposing all the infants to be extracted alive, not one-half will reach the age attained by their mothers." The limits for embryotomy should be somewhat lowered, with a dead fœtus; also, *cæteris paribus*, if the woman has been long in labor. Section is sometimes called for where delivery is prevented by pelvic tumors or inflammatory deposits.

The improved Cæsarean operation has been done about one hundred times. Sänger stated, when the number had reached seventy-six, that over seventy-six per cent. of the mothers had been saved. Of these, fifty-two were operated on in Germany, saving over eighty-eight per cent. of the mothers. Perhaps the most successful series was the first sixteen cases, under five operators, in Leipsic and Dresden, saving fifteen women and all the children. Leopold has had the largest experience, and has saved over ninety per cent. of the mothers. Lusk heads the American list

with three successful cases. The first five American cases were all fatal from late operation. The results of the later ones are much better. Finally, the Cæsarean section may be considered absolutely necessary in pelves with one and a half inches, or less, in the conjugate, and under certain other rare conditions, and the operation of election with a conjugate not above two and a quarter, perhaps two and a half inches, since it is not more dangerous than embryotomy, and saves the child. Above this limit, section should only be done at the request of the mother. With a dead fœtus, embryotomy should be done with a conjugate above two inches, provided the transverse diameters are not too contracted. The German results show that the true maternal mortality of the operation, skillfully done, is about fifteen per cent. The chances for the fœtus being born alive are approximately those of natural delivery.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

It has been our painful duty on more than one occasion to call attention to certain defects in the editorial management of the *Journal of the American Medical Association.* If these defects had been in mere matters of taste, we would perhaps not have criticized them; but they were of a more serious character, and, in our opinion, required correction if the Journal of the Association was ever to become an example to all other journals, of the highest type of medical periodicals. These criticisms seem to have had a salutary effect; for there has been a noticeable amendment in the Journal since they were made, in regard to some of the matters criticized.

A recent number—that for June 23—contains, however, a long letter, signed by one of the assistant editors of the *Journal,* and addressed to the editor of the MEDICAL AND SURGICAL REPORTER. It is dated June 11. The readers of the Journal might suppose it to be a copy of a letter sent at that time to the person to whom it is addressed. But the writer, and the editor of the Journal, will probably be less surprised than its innocent readers to learn that the person to whom the letter is addressed first saw it when the mail brought him, on June 25, the copy of the Journal for which he subscribes.

The matter of this letter is an attempt, in two and a half pages, to weaken the force of a very short statement made by a correspondent of the REPORTER, writing from Cincinnati at the time of the last meeting of the American Medical Association.

We will let our correspondent's statement go as it stands and make no attempt to add force to what he says. The members of the Association may make up their minds in regard to the matter without urging from the REPORTER. But we may reply with propriety to an insinuation contained in the letter in the *Journal* that the REPORTER has an interested motive in criticizing the Journal. The fact is that we wish to see the *Journal* fulfilling its legitimate office in the very best way, and if we call attention to its faults, it is with the hope that it will mend them. To point out what seems to us to be ill-advised, on the score of principle or of sound policy, is a kindness such as Solomon appreciated, when he said: "Better are the wounds of a friend than the kisses of an adversary."

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained, upon receipt of price, from the office of the REPORTER.]

THE RELATION OF ALIMENTATION AND DISEASE. By J. H. SALISBURY, A.M., M.D., LL.D., Member of the Philosophical Society of Great Britain, etc. Royal 8vo, pp. xi, 332. New York: T. H. Vail and Company, 1888.

One should treat with respect the utterances of a man who has carefully studied any subject for years, and who has come to entertain strong convictions in regard to it, even if one fails to recognize these convictions as correct. For this reason the book before us deserves careful consideration. It contains the conclusions reached by over thirty years of investigation of the most minute and laborious kind; and if these conclusions are not in accord with the opinions of most medical men, they are not to be dismissed with a sneer. We greatly fear that this will be their fate, however; for they are so extreme that they are sure to excite the criticism that the author has

followed the gleam of light which broke upon him, as he says, in the beginning of his studies, so exclusively that he has failed to see the countless other gleams which have fallen upon the world during their continuance.

The dominant idea of the book is that defective alimentation is the primary cause of almost all human ailments, and that proper alimentation is the cure for them. In a limited sense we think this is true; but we cannot follow Dr. Salisbury to his full conclusions.

Our limited space does not admit of a detailed analysis of his book, which we can commend as containing much food for thought. If it does not wholly convince the reader, it will furnish suggestions which will be of great value, and will certainly impress the reader with the industry and ingenuity of the author.

THE CUSTOMARY TREATMENT OF THE HAIR CONSIDERED IN RELATION TO THE REMARKABLE PREVALENCE OF PREMATURE BALDNESS IN THE UNITED STATES. (Author's name not given.) Duodecimo, pp. 20. St. Louis: Arthur R. Deacon, 1888.

The publisher of this monograph states that it is designed for popular reading, but the correctness of its claims and value of its teachings should first be determined by medical men. As having given some thought to the care of the hair, we take pleasure in commending this unpretentious little book to the attention of our readers. It bears hard, but not unjustly, upon the practice of barbers, and especially upon the process called "shampooing." This, we believe with the author, to be injurious to the hair and to be strongly deprecated. We do not share his opinion that cutting the hair short in summer is prejudicial to its health, or that it is advisable to apply oil habitually to the hair. But most of his opinions coincide so entirely with our own, that we think his book is a very sensible one.

CORRESPONDENCE.

Immediate Perineorrhaphy.

TO THE EDITOR.

Sir: I have just read an editorial in MEDICAL AND SURGICAL REPORTER of June 9 on the subject of immediate perineorrhaphy. Like yourself I am surprised that anyone will delay so important an operation. Without going into details in regard to the pathology, treatment, and results of the accident, I will relate a few cases that have occurred within my obstetric experience of nearly twenty years in order to prove that immediate perineorrhaphy is the proper and only procedure worthy of practice and advocacy. My first case was that of Mrs. Claridez, a primipara. The rupture of the perineum was caused by the shoulders after a protracted unaided labor of twenty-four hours. Within one hour after the uterus was cleared of all detritus, etc., I proceeded to do up the rupture, which was a recto-vaginal one, with three deep silk sutures. After the sutures, I applied an ointment of vaseline and iodoform above the torn surfaces, rectal and vaginal. The ointment was applied every morning, after washing the parts well with carbolic acid soapsuds until the parts began to unite well, and then for a few days the parts were dusted once each day with bismuth subnitrate. In three weeks from the day she was ruptured, and at about the time for her to get up, she was well and sound. My second case was that of a young mulatto girl 13 years old when she was confined of her first child, weighing 10½ pounds. Rupture of the perineum occurred on the emergence of the head. Like the first case, it was a recto-vaginal rupture, and a deep one. Within two hours after the accident, I had the perineum well stitched together with three deep sutures, and the after-treatment was just like the first—the parts kept clean with carbolic acid soapsuds, and vaseline and iodoform ointment the first three or four days, and then dusting the surfaces once a day with bismuth. She recovered and was up all right in due time. My third case was that of Mrs. Cummins: first child; rupture of perineum by the shoulders. It was a partial rupture of rectum and vagina. As soon as she was cleared and rested, I sewed up the perineum with two superficial silk sutures, kept the parts well anointed with the vaseline and iodoform ointment for four or five days, and then began dusting the parts with bismuth as usual. This case, like the others, made a complete and rapid recovery in three weeks. My fourth case was that of a colored woman who had given birth to four children and was ruptured in her fifth confinement by an old midwife endeavoring to "turn a shoulder presentation into a head," as she called it. This rupture was a severe and extensive one, and had been done six hours before I saw it. I closed it up as I had all the other cases, and in three weeks she was ready to resume her usual household duties. And now to close my remarks, I will say that I never tied a knee or confined the legs in any way—simply directed the patients to keep their thighs together and to avoid spreading them apart as much as possible. In each case, as soon as they would come from under the effects of the chloroform given during the operation, I would give them a dose or two of powdered opium, enough to quiet them and hold the bowels in check two or three days; then I would order an enema of soapsuds and molasses to unload the bowels, after which I would give more opium and check the bowels two or three days more, then use the enema as before. In two of the cases,

I had to draw the urine the first two or three days, but no longer. These cases were not allowed to eat solid food of any kind for the first week, but were fed on soups, gruel, and milk. Each one of them, except the mulatto girl, has borne from two to four children since their respective ruptures without lacerating or in any way injuring their perineums. They are all alive, and are living willing witnesses to the success, propriety, and certainty of the immediate operation. I will do the immediate operation in every case coming under my care, regardless of what Fordyce Barker, Charpentier, or any other so-called luminary says. Common sense and every other reason all dictate an immediate operation. Were I disposed to do so, I could report several cases of ruptured perineums in the practice of neighboring physicians that were treated weeks and months after the accidents, which have never recovered right and properly, and never will.

If you wish to publish this do so, and if not, read it well and cast it aside. It is especially for you, and I hope it will afford you some encouragement to advocate the immediate operation of perineorrhaphy.

Yours truly, R. P. Davies, M.D.

Petty, Texas, June 20, 1888.

Notes and Comments.

Operation for Chronic Inflammation of the Spermatic Cord.

Dr. Horatio H. Johnson reports the following interesting case in the *Boston Med. and Surg. Journal*, May 24, 1888: Mr. P., seventy-five years old, a stout hardy farmer, seven years ago noticed a swelling in the groin, which he supposed to be a rupture, and, without any surgical advice, applied a home-made truss, which at times made him so sore, and gave him so much pain, that he would be obliged to discontinue its use; finally his condition became such that he sent for medical advice, and, the physician recognizing the necessity of surgical interference, on the following morning Dr. Johnson received a telegram to see the patient in consultation. There was found a hard unresisting swelling, extending from midway between the superior spinous process of the ilium and the symphysis pubis down to the testicle, which was considerably drawn up in the scrotum. The bowels had moved regularly each day unaided by laxatives, which led him to conclude it was not a hernia, though previous to his visit the patient had been etherized and taxis had been thoroughly tried. The case was diagnosticated as chronic inflammation of the spermatic cord, and it was deemed prudent to resort to surgical means for the patient's relief. Dr. Johnson removed five and one-half inches of the spermatic cord, with testicle attached, ligating above all signs of disease. The cord measured seven inches in circumference, and was well advanced toward suppuration. The patient was confined to his bed about five weeks, with very little rise in temperature or acceleration of the pulse, and the wound healed for the most part by first intention. The ligature on the pedicle remained twenty-five days. The patient is now about, and has made a complete recovery from the operation. Dr. Johnson regards the diseased mass as the result of continual irritation from the wooden pad worn for supposed rupture.

Phosphine.

At the meeting of the *Société de Thérapeutique*, of Paris, May 9, 1888, M. Dujardin-Beaumetz gave an account of experiments he had conducted in regard to the value of the dinitrate of diamidophenylacridine, or chrysaniline, known in commerce as "phosphine," as a substitute for antipyrine. This drug is a red powder, which, when dissolved in an alkaline liquid, gives it a phosphorescent appearance. M. Dujardin-Beaumetz administered the drug in a one per cent. solution in doses of from about seven to about fifteen grains. He found that the smaller dose produced distinct analgesic effects; but that when the larger dose was given it produced marked gastric disturbance. His conclusion is that phosphine cannot be admitted as a therapeutic agent, because of these disturbances.

Poisoning with Hydrochloric Acid.

M. Vaquez has made an autopsy on a patient who died three days after having taken six and one-half ounces of hydrochloric acid. The caustic passed into the air-passages, and there produced serious lesions of the trachea and bronchi, while the larynx remained almost unharmed. The cause of death was suppurative broncho-pneumonia. The tongue, pharynx, œsophagus were but slightly attacked, but there were profound lesions of the stomach. The intestine was healthy, showing that the poison had been retained in the stomach. This immunity of the intestines is very remarkable.—*Bulletin Médical*, May 20, 1888.

Suprapubic Lithotomy.

Dr. W. W. Keen, of Philadelphia, has lately removed a stone weighing ʒvii from a man's bladder, by suprapubic cystotomy, the operation being followed by an uninterrupted and rapid recovery.

Engraving of Dr. Cornelius R. Agnew.

At the last meeting of the Ophthalmological and Otological Section of the New York Academy of Medicine, it was resolved that a committee be appointed to obtain a good photograph of the late Dr. Cornelius R. Agnew, for the purpose of having engravings suitable for framing made from it. Members of the profession who desire such an engraving, accompanied by an autograph signature, should send their names and addresses to the Secretary of the Committee, Dr. Charles H May, 640 Madison Avenue, New York City, at once. When all names have been recorded, those who have requested a copy of the engraving will be notified of the cost of it, either by the publisher or by the committee having the matter in charge. It is understood that the engraving will be furnished at cost price.

China Grass, a New Antiseptic Surgical Dressing.

H. Bendelack Hewetson, in some remarks on China grass made before the Leeds and West Riding Medico-Chirurgical Society (*Lancet*, June 23, 1888), states that China grass is a soft, silky, very highly absorbent fibre used in various manufactures. The combings form an elastic silken wool, which, when treated with 4 per cent. of salicylic acid, makes an excellent antiseptic absorbent surgical dressing. It is also relatively much cheaper than, so far as Mr. Hewetson knows, any of the usual dressings used in surgery. Its chief value consists in the way in which it absorbs discharges from a wound, rendering it very dry, and preventing the poulticing of the wound, as it were, when the latter is bathed in discharges under less absorbent materials. A considerable quantity is required in cases in which the discharges are free, and it is perhaps well to interpose some open-meshed gauze between the dressing and the wound, so as to prevent the China grass from sticking to the wound when an attempt is made to remove the dressing. He states that he has also observed that, under the pressure of bandaging, the material still retains its absorbent qualities and does not cake when properly teased out before use.

Physiologists on Mont Blanc.

Three enterprising Frenchmen went last summer to the top of Mont Blanc for the purpose of making a series of meteorological and physiological observations, and remained there for two or three days in order to obviate the errors which, so far as physiological observations are concerned, would be inevitable if made while they were still suffering from the extreme fatigue incidental to so laborious an ascent. As it was, none of them had the courage, on attaining the goal, to put up the tent, etc., which, with great difficulty, had been brought up; and they fell asleep with their heads on the boxes of instruments. The thermometer, when placed on the snow, registered 19° C. below zero. M. Richard and one of the guides suffered from severe headache, with feverish symptoms. The least effort—even ordinary movement—caused such fatigue that they were compelled to lie down during the greater part of the day. They had masks to preserve the skin of the face from the biting cold, and the usual spectacles to avoid snow-blindness. The travelers suffered from almost complete anorexia, and they noticed that tea immediately made them ill. The second day, tracings were taken of the pulsation of the carotid and radial arteries. One of the guides was quite prostrated with headache and high fever, and was only got down with great difficulty. Once down, a good meal, a denser air, and a milder temperature soon restored them to their normal condition of health.—*British Med. Journal*, May 26, 1888.

Phenacetine.

Professor Rumpf, of Bonn, in a paper read before the Cologne Medical Society last month, gave his audience some account of his experience of phenacetine. The conclusions to which he came were that phenacetine is free from any unpleasant effects, and that it acts with remarkable certainty as an apyretic, the dose being for adults eight grains and for children from three to four grains. In doses of fifteen grains it is valuable in neuralgia (*a*) where the affection is due to vasomotor disturbance, (*b*) in the lancinating pains of tabes and neuralgia due to chronic neuritis, and (*c*) as a palliative in other forms of neuralgia. Being insoluble, phenacetine may be administered in capsules, or it may be placed dry on the tongue. Professor Rumpf has never found nausea, vomiting, failure of the heart's action, or cyanosis follow even fifteen grain doses.—*Lancet*, June 23, 1888.

NEWS.

—Dr. Egbert H. Grandin has resigned from the Department of Gynecology at the New York Polyclinic.

—The Lehigh Valley Medical Association will hold its eighth annual meeting at the Paxinosa Inn, near Easton, Pa., August 15.

—Dr. R. G. Penn, who was convicted of murder in Copiah County, Mississippi, five years ago, has been pardoned by Governor Lowrey.

—Dr. Abraham T. Lowe died at Ashburnham, Mass., July 4, at the great age of ninety-two years. He was graduated at Dartmouth College.

—The *Sacramento Med. Times*, July, 1888, states that a mild form of scarlet fever is at present to be found in a number of places in California.

—The physicians of St. Joseph's Hospital, Reading, Penna., have threatened to resign unless homœopathic treatment of patients be prohibited.

—Dispatches from New York state that a patient suffering with small-pox was landed at Sandy Hook from the White Star steamer "Celtic," and was subsequently taken to Elberon on the regular train.

—Typhoid fever is reported to be epidemic in Canton, Mass. There have been two deaths, and fifty cases are now under treatment. Cesspool drainage into a well is supposed to have caused the disease.

—A committee representing the Pennsylvania and Maryland Union Medical Society held a meeting at West Chester, July 6, for the purpose of arranging to hold the annual reunion of the Inter-State Association at Birmingham Park, on the Brandywine, August 30.

—It is stated that the towns on the upper Penobscot, Maine, are suffering from the ravages of caterpillars. In Chester, Maine, they have stripped the orchards and are now attacking the forests, and literally clearing the poplar and green hardwood trees of their foliage. Similar reports are said to come from other Maine towns.

—Governor Beaver, of Pennsylvania, has appointed James B. Scott, of Pittsburg, a member of the State Board of Charities, in place of Geter C. Shidle, who resigned. He has reappointed the following members of the Board whose terms had expired: George I. McLeod, M.D., and Thomas G. Morton, M.D., of Philadelphia, and J. W. C. McNeal, of Gettysburg.

—The celebrated ophthalmologist and physiologist, Professor F. C. Donders, of Utrecht, celebrated his seventieth birthday on May 28, in the presence of numerous scholars from all parts of Europe. Baron Roëll transferred to Dr. Donders 56,000 marks (about $14,000) which the latter has determined to use for the purpose of assisting students of high promise in pursuing their studies in ophthalmology and physiology in one of the universities of the Netherlands.

—As recorded some time since, the town of Bournemouth has laid down plants for the distribution of salt water for municipal purposes. These works were opened on May 15, and consist of two brick water-towers, with cast-iron tanks, having a capacity of 25,000 gallons each, of a total height of 58 and 55 feet respectively, the level at the top of the tank being 188 feet above sea-level, and about a mile distant from the sea; together with 57 hydrants, 57 water-posts, and 80 sluice-valves. There are about 6½ miles of 6-inch pipe, about seven miles of 4-inch pipe, and about 390 yards of 8-inch suction-pipe. The total cost of work is about $45,000, and they have a pumping capacity of 100,000 gallons per day. It is estimated that the cost per 1,000 gallons will be about threepence half-penny.—*Engineering and Building Record*, June 16, 1888.

HUMOR.

Little Emily—Do you like coffee, Mr. Watkins? Old Mr. Watkins—Certainly, dear. Little Emily—Well, you make such a noise swallowing, I thought perhaps it hurt you. Does it?

Patient (to young Sawbones, who is about to cut off his arm)—Do you think the operation will be successful, doctor? Young Sawbones—Of course it will; I'll have that arm off in less than ten minutes.

The latest bulletin.—Editor: "Where is the cable about the Emperor's health?" Assistant: "None came." Editor: "That so? How was he yesterday?" Assistant: "Worse." Editor: "Make him better to-day."—*Tid-Bits.*

A mistake in diagnosis. — "I find, madam," said a young physician, "that your husband is suffering from overwork." "And will he have to give up his place under the Government?" she asked, anxiously. "What's that? Is he a Government official?" "Yes, sir." "H–m! I'll diagnose his case again. He probably needs exercise."—*N. Y. Sun.*

OBITUARY.

A. Y. P. GARNETT, M.D.

Dr. A. Y. P. Garnett died on the night of July 11, of heart-failure, at Rehoboth Beach, Delaware. He was born in Virginia in 1820, was graduated from the University of Pennsylvania in 1841, entered the United States Navy as assistant surgeon the same year, was promoted surgeon in 1848, and resigned in 1850 in order to accept the Professorship of Clinical Medicine in the National Medical College of Washington. At the breaking-out of the rebellion, he left Washington and became Surgeon General of the Confederate Army. When the war was over, he returned to Washington and was again elected a Professor in the National Medical College. He served as President of the American Medical Association at its last meeting. He contributed many valuable papers to medical literature, the last being the Presidential Address before the American Medical Association, in which he spoke very earnestly in favor of elevating the standard of medical education in the United States.

JOHN LIVINGSTON LUDLOW, M.D.

Dr. J. L. Ludlow, one of the most widely-known physicians of Philadelphia, died June 21, 1888, in the sixty-ninth year of his age. His death was caused by prostration. He had been gradually failing in health since March, and for the past six weeks had been confined to his home.

Dr. Ludlow was born at New Brunswick, N. J. He passed his early boyhood in Albany, and, when fourteen years old, came to this city with his father, who in 1834 was elected Provost of the University of Pennsylvania, and who occupied this position for eighteen years. Dr. Ludlow was graduated at the University with honor in 1838, and afterwards studied medicine, finishing his medical course at the same institution in 1841.

During his long career as a practitioner, he occupied many positions of influence and honor. He was for thirty years one of the visiting physicians to the Philadelphia Hospital, and last year, when he retired from this position, had conferred upon him the honorary title of Emeritus Physician. At the time of the organization of the Presbyterian Hospital, he was elected a visiting physician and served until his death.

Dr. Ludlow was a Fellow of the College of Physicians of Philadelphia, and a member of the State and County Medical Societies, as well as of a number of other societies. Dr. Ludlow was an earnest and conscientious man and a devoted physician. His scientific ideas were largely those of the last generation, and he regarded with some distrust a number of the changes in opinion which have taken place during the last two or three decades. He was a man of warm heart, and enjoyed the regard of old and young alike in the profession. He was especially kind to his juniors, and those who served as resident physicians in the Philadelphia Hospital while he was connected with it were always sure of his sympathy and aid in any trying circumstances, and they especially will cherish his memory with affection and gratitude.

DR. RACHEL L. BODLEY—Resolutions.

At a meeting of the Faculty of the Woman's Medical College of Pennsylvania, held June 20, 1888, the following action was taken on behalf of the death of Professor Bodley:

Whereas, Our honored Dean and Professor of Chemistry, Rachel L. Bodley, has been suddenly removed by the hand of death from the arena of earthly activities, in so many of which she was deeply interested—

Resolved, That we, her colleagues in the Faculty of the Woman's Medical College of Pennsylvania, recognize in the removal of our senior member the loss of one most familiar with the historical and traditional features of our college and its past work.

She was thoroughly acquainted with the arduous duties of Dean, which she performed most ably and acceptably, and in which her wise administration secured for the college friends wheresoever her influence was exerted.

She was keenly alive to the personal as well as educational requirements of the students, so many of whom, coming as strangers from far distant lands, found in her a friend earnestly solicitous for their welfare, and ever ready to do all in her power to further their interests.

She was an able teacher of chemistry, striving successfully by word and illustration to elucidate the intricate problems of her branch.

Religiously devout, she at once placed before those with whom she came in contact a high standard socially and morally, and did much to establish the same for the college, to the services of which her efforts and indeed her life were so ungrudgingly, unsparingly, and unceasingly devoted.

Possessing an acquaintance among peoples in all lands through her college relations and affiliations, her usefulness to us and to the world can scarcely be overestimated, so varied and extensive had it become.

As a friend, she was ever genial, kindly, and courteous, and we shall greatly miss her quiet dignity in our Faculty meetings. In the entire round of college work, with the extensive ramifications of which she was so thoroughly familiar, we feel our loss to be almost irreparable.

Resolved, That these resolutions be spread on the minutes of the Faculty, and a copy of them be sent to her aged mother.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

College of Physicians and Surgeons

OF BALTIMORE, MD.

The Preliminary Course begins September 15th, 1888.

The Regular Session will open October 1st, 1888, and close about March 15th, 1889.

Attendance upon two full sessions is required for graduation.

The Clinical facilities of this school will be further increased by the new "City Hospital," which has a capacity of 300 beds.

For Catalogue, containing full information as to fees, etc., write to

THOMAS OPIE, M.D., Dean,

Cor. Calvert & Saratoga Sts., Baltimore.

Microscope Accessories,

Mounting Materials,

Dissecting Instruments,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers, with Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE. 2107 Penn. Avenue, Pittsburgh.

WANTED.

A RESIDENT PHYSICIAN FOR THE JEWISH HOSPITAL.

Applicants must be graduates of a regular medical college, unmarried, able to speak English and German. **Salary $800.00,** and living at the Institution.

No private practice permitted.

Address in writing, stating age, the college graduated from, and other particulars, to

Clinical Lecture.

HYSTERIA AND SPIRITISM.[1]

BY PROFESSOR J. M. CHARCOT,

PROFESSOR OF THE FACULTY OF MEDICINE, PHYSICIAN TO THE SALPÊTRIÈRE, ETC., ETC., PARIS, FRANCE.

Gentlemen: It is incontestable that everything which vividly affects the mind, everything which powerfully stimulates the imagination, favors the development of hysteria in persons predisposed thereto. Of all causes productive of these traumatisms of the cerebral functions, there is perhaps none more efficacious, and whose influence has been oftener acknowledged, than inordinate belief in the marvelous, in the supernatural, a belief which is fostered and exaggerated by excessive religious observances or—to descend to a kindred order of ideas—by spiritualism and its practices. It is sufficient to recall to mind certain facts which are matters of history, such as that of the "Possessed Maiden of Louvres" in the sixteenth century, whose imagination had been kept in constant tension, before her "possession," by the lost spirit which reappeared every night in the house where she lived;[2] and there is a recent interesting instance of an epidemic of hysteria affecting six children of one family in Brétagne whose minds had been fed with fantastic stories in which witches and ghosts played the principal part.

[1] Advance sheets of a new volume about to appear from the press of G. S. Davis, with the sanction of the professor. Translated by E. P. Hurd, M.D.

[2] Procès verbal fait pour delivrer une fille possédée par le malin esprit à Louviers, 1591. Bibliotheque diabolique, 1883.

It has been my lot to observe one of these little family epidemics, the principal actors in which I am going to present to you to-day. This epidemic merits a particular description, as much with reference to its mode of development as for the light which it gives in the study of hysteria in children, and particularly in young boys. It is in a military penitentiary that the facts occurred which I am going to relate.

Life in a penitentiary must be dreary enough at the best; moreover, by reason of the discipline which must necessarily prevail in such institutions, even the apartments of the military keepers cannot but partake of the gloom and severity of the place. The lodgings occupied by Monsieur X., adjunct lieutenant, are situated on the third floor; access thereto is obtained by a dark stairway; the apartment itself is insufficiently lighted, for all the windows, which look out upon the prison yard—which, it is true, is a spacious one—are situated high up, near the ceiling, and admit but little light. Monsieur X., who has lived in the penitentiary three years and a half, is forty-three years of age; he seems to be quite intelligent, although his military career has been one of slow and moderate advancement; I shall say more about his mental state presently. His general health is good, and there are few pathological antecedents on his side. At the age of thirteen, he suffered from an affection which was febrile at its commencement, but was followed by a delirious state which lasted six months.

Madam X., aged thirty-six years, and married since 1879, is a very nervous woman; she is quick-tempered, emotional, and fretful; has, however, never had convulsive attacks of any sort. It is not so,

however, with her mother, who died in March, 1884, at the age of seventy-two years, of a cerebro-spinal affection, and who every year had two or three returns of well-marked hysterical fits. We may note, finally, that her father was a constant sufferer from rheumatism.

Monsieur and Madam X. have had four children; three are still living; the fourth died, probably of athrepsia, at the age of two and one-half years.

You see before you the oldest of the three living children—Julie, aged thirteen and one-half years; she was born before full term—at seven and one-half months—and she remained a long time weak and puny, having been brought up on a bottle. For the last three years, she has been boarding at a convent in the neighborhood of the penitentiary. From her infancy, she has been very nervous. At the convent, as at home, she has been unruly and difficult of management, laughing and crying for the most trifling cause. In 1883, she menstruated for the first time; these first monthly periods were accompanied by violent cramps; menstruation then ceased, and has not since returned. Every year, she comes home to spend her vacations with her parents at the penitentiary. It is proper to state that, prior to the events I am about to relate, she had never witnessed any convulsive crises.

I also bring before you the younger of the boys, François, aged eleven years, who is pale and anæmic like his sister. At the age of four months, he had convulsions, and from the time that he was two years old he suffered from pains in the joints of the lower extremities, knees and feet. These pains, which have lately returned on various occasions, are sufficiently severe to keep him in bed. He takes his meals at a boarding-house near the penitentiary, and comes home at night to sleep.

Jacques, the elder of the boys, aged 12 years, also anæmic, shares his brother's mode of life. For several years, he has had convulsive tics, affecting chiefly the mouth, as you can yourselves see. During the month of August last, the entire family were home passing the holidays together—the father and mother busy with their usual occupations, the children playing together in the yard of the penitentiary, almost always alone, for belonging to the families of the other officers there was only one child, four years of age. Life in a house of correction must, as I have before said, be very tiresome: apart from the regular routine, there is little in the way of diversion; hence, in order to break this monotony, the wives of the prison-officers had been in the habit now for more than a year of devoting themselves with passionate interest to spiritualistic practices, holding séances which were conducted every other day by a female friend of one of them. This diversion was very much to their taste; in fact, they all became pronounced spiritualists, and none more so than Monsieur and Madam X. The latter, moreover, applied herself eagerly to the reading of books treating of "occult sciences," books which she did not hesitate to allow her daughter to read. As for Monsieur X.—who had at first been quite indifferent to spiritualism—since the month of March, 1883, he never missed taking part in table-tipping on Fridays, it having been revealed to him by raps one day that on some Friday he would become a medium and have the power to call up the spirit of his mother. So it happened that Julie was present at a spiritualistic séance during the Easter holidays; this did not, however, much affect her. Coming home during the August vacation, she had already participated in several "circles," in which, however, she had had no part except to lay her hands upon the table; but on Friday, the 29th, her father made another attempt to find if his turn for being medium had not come. He interrogated the table, and the latter, instead of designating him, as he hoped it would, replied by raps: "Julie shall be medium." The whole of Friday was devoted to a séance which was almost uninterrupted. The next day, at nine o'clock in the morning, the family and two or three neighbors again formed a circle. They called up the spirits of various persons, and, about three o'clock in the afternoon, the table rapped an order for Julie to write. She thereupon seized a pencil, but the same moment her arms became stiff and her eyes fixed. The father, in his fright, threw a glass of water in her face. She came to herself, but her mother, having a presentiment of the danger, forbade her to have anything more to do with table-tipping. She did not, however, realize the influence of her neighbor whose friend was a medium, and attended the séance in her company. This neighbor, desirous of communicating with the spirit of her sister, took Julie home with her, and the séance recommenced. About seven o'clock, the table tipped, the spirit was declared present, and Julie said to it: "Please to sign your name." Immediately, she herself, in her quality of medium and "under the inspiration of the spirit," seized a pencil with trembling hand and

wrote "Paul Denis" with a flourish. The handwriting was that of a man; the P and D, moreover, were written in such odd characters that the young girl has never since then been able to trace letters like them. The signature was no sooner terminated than the hand that had written it was convulsed. Then Julie, with a shrill laugh, rose immediately, and, like one mad, in wild delirium ran back and forth through the house, uttering inarticulate cries, then rolled over and over on the floor, presenting a series of hysterical paroxysms characterized chiefly by contortions (clonism). The next day and the following days, the fits reappeared very often—twenty to thirty a day. So affairs went on till the fifteenth of November, Julie continuing to have convulsive orises and being little benefited by the application of divers means, and, in particular, of hydrotherapy.

Several days previously, François, the younger of the boys, who, like his brother, always took a great interest in spiritualistic performances, was attacked with pains in the joints, which, at that time, kept him in bed. All at once, on the 15th of October, he rose in bed and exclaimed that he saw lions, wolves; then he leaped out of bed, pounded the doors, declared that he saw his father a corpse, that he saw robbers, whom he attacked with a short sword; then he lay down and rolled on the floor, crept on his belly, and assumed certain well characterized passional attitudes. Two days later, Jacques had an aggravation of his facial tics; then, seeing his mother weeping, he exclaimed: "I will kill myself if you weep!" Then attacks of temporary delirium came on, during which he muttered incoherent phrases and saw robbers and assassins, whom he tried to strike.

It was on the 9th of December that the father and mother, in their affliction—all treatment having been without avail—brought their children to the Salpêtrière. Separation and isolation were becoming more and more necessary, for, when one of the children had a fit, the others speedily followed the example.

Julie, whose pathological antecedents you now know, and whose age is thirteen and a half years, is tall and stout for her age, quite well developed, although, as I told you, her courses, which came on once or twice in 1883, have not yet been permanently established. Despite of what her mother has informed us, she seems to be of a mild and quiet disposition. On the first day of her entrance, as well as on the subsequent days, she had several fits which were in general characterized as follows: All at once, sometimes after a brief and variable *aura*, she fell backward, the arms were separated from the trunk, the hands being in pronation, the fingers clinched. Then quite frequently supervened one or more attacks characterized by a unilateral arching of the body; and lastly the clonic phase presented itself, in which the body was jerked back and forth, the head at times was almost brought in contact with the pelvis, or the arms were projected violently in the air, the head still resting on the pillow. During the attack, Julie uttered moans, had fits of laughter, but did not speak. The fit, which was composed of a series of seizures similar to what I have described, lasted quite a long time—three-quarters of an hour, an hour, or an hour and a half. It was easy to stop or provoke a fit at will by pressing on one of the hysterogenous points which the patient presented. Julie, in fact, possesses certain permanent hysterical stigmata; although she has neither cutaneous anæsthesia nor ovaria [ovarialgia], she has numerous hysterogenous zones, situated opposite each other, on the two breasts, on both flanks (externally), on both calves, and the two external malleoli, and on the internal aspect of the right elbow joint. The examination of the eyes, made by M. Parinaud, gives results which are characteristic. There exists, in fact, on the right, a very marked contraction of the visual field; moreover, not only is the circle of red situated outside of the circle of blue, but it even plainly extends outside of that of the white light. The same phenomena exist on the left side, though less pronounced. The other special senses are intact.

François, the youngest of the boys, aged eleven years, has also certain permanent stigmata apart from the seizures which I have just described. Thus, on the morning of his admission, we noted an area of anæsthesia embracing the whole face; this patch was, however, variable, for the following days the insensibility was limited to the median region of the forehead and nose. The rest of the external integument is notably hyperæsthetic. All the special senses are affected; the taste is totally abolished, the insensibility of the tongue is complete, the pharyngeal reflex no longer exists, the pituitary membrane and the smell are in similar condition, the external auditory meatus is insensible, and hearing is very obtuse. The examination of the visual field is also very demonstrative; the contraction is quite marked on the left, and not only is the

circle of red outside of the blue, but it also extends beyond the circle of white light. On the right, the contraction is less marked, and there is no transposition of colors. François has from one to five fits every day; some of them last two hours. He presents clearly the phenomena of minor and major hysteria (*petit* and *grand mal hysterique*). The first, or minor hysteria, is characterized by a contracture of the orbiculares of both eyes, which may last from three to five minutes without loss of consciousness; or another symptom referable to the *petit mal* may present itself: the boy smites with his fists or stamps with his foot, and pronounces certain incoherent words, and all is over. But generally the preceding phenomena are followed by a series of characteristic paroxysms constituting a fit. The upper and lower limbs become rigid, the eyes are closed, the body is stiffly bent into a bow. Then the boy throws himself upon the floor, creeps on his belly, smites the floor, crying out at the assassin of his hallucination; he struggles and kicks and endeavors to defend himself against his imaginary foes. The tonic phase is now repeated, and the fit is thus constituted by a series of accessions, one set of phenomena running into another or predominating over the others. It is a remarkable circumstance that, when you compress the left hand, the fingers of which are extended, you arrest the paroxysm instantly. You cannot, however, provoke an attack in this way. The skin over this region does not present any disorder of the sensibility.

Jacques, aged twelve years, pale and anæmic like his brother and sister, is the least sick of the three, though he has one, two, and sometimes three or four attacks every day. While there are not, in his case, any permanent stigmata, there is a marked preponderance of the *petit mal* over the *grand mal*. We know that, before these fits came on, he had convulsive tics of the face; these are now exaggerated, especially at the beginning of the seizure. He makes wry faces, the labial commissures are drawn outwardly; he mumbles, closes his eyes, utters certain incoherent words, and all may be over. But sometimes, as a sequel of these phenomena, or even at the outset, the eyes close, the body stiffens, is arched like a bow, then the child starts and runs or walks to and fro, speaks in a loud tone of voice, cries out at some imaginary thief, and finally throws himself on his bed, when the fit ends, or another one begins, lasting rarely longer than a quarter of an hour.

These facts have seemed to me to merit a particular attention. These are not, in truth, fugacious symptoms of hysteria which these children present. Julie has been sick for four months, and, if the isolation seems to have somewhat calmed her crises, as well as those of her brothers, it is no less true that the fits threaten to continue yet a long time, for you cannot bring together these children without all three of them immediately having a convulsion. The whole history of this little family epidemic is, moreover, very instructive. It makes you a witness of the genesis and evolution of the disease in a family of nervous and arthritic persons under the domination of two diatheses whose alliance is a most fruitful source of neuropathy. It gives you an idea of the influence exercised by the kind of life one leads and the conditions of habitation. Lastly, it indicates clearly the danger there is, especially to persons nervously predisposed, in superstitious practices, which unfortunately have for them so great an attraction, and in that constant tension of mind and imagination to which those are brought who apply themselves to spiritistic performances and the search of the marvelous, an occupation in which children take so much delight.

COMMUNICATIONS.

RESPIRATION EXERCISES; RELATING TO THE DEVELOPMENT OF THE CHEST CAPACITY AND MUSCLES OF RESPIRATION.

BY A. H. P. LEUF, M.D.,
DIRECTOR OF PHYSICAL EDUCATION AT THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

The function of respiration has for its main object the abstraction of oxygen from the air and the exhalation of carbonic oxide from the blood. To this end there are necessary blood and air in constantly moving currents, and almost in contact. Any imperfect interchange of oxygen and carbonic oxide causes a sensation of suffocation, which increases in proportion as the process is incomplete. The inadequacy of oxygenation may depend upon a retardation or suppression of either of these currents. If the air supply is defective, it is because of insufficient chest capacity due to weak muscles, or an inelastic chest, or inability to use properly the respiratory muscles. Of course no account is now taken of advanced lung disease or of either internal or external

mechanical obstruction of the air-passages. If, on the other hand, the blood supply is defective, the cause is in the circulatory apparatus, and, as a rule, mainly in the weakness of the heart. That both of these shortcomings may be rectified in most instances can not admit of a reasonable doubt. In this paper, I shall confine myself to exercises relating to the chest and lungs and the circulating air.

Of all the books issued on gymnastics most are good; I may say very good; but, from the view of the athlete mainly. Their scientific value from a medical standpoint does not meet a critical requirement. All the writers I have seen have a crude notion of myodynamics, and yet even one of these, in a recent work, tells of his astonishment at having noticed that remarkably few physicians are even as well versed as he on this subject. Let me say at once that the knowledge of myodynamics usually possessed by even well informed physicians, and by those undergraduates well known to their teachers for their acquaintance with anatomy, by no means gives the same facility of analyzing complex muscular actions as practical anatomists have. From this point of difference arises a defect that is so serious as to endanger many lives. When a man begins the practice of medicine, he should be qualified to do his work, and if he is conscientious and modest, he will not jeopardize a trusting patient's life when he is not certain of his own ability to diagnose and treat the disease. So *should* it be in the prescribing of exercises for either well or unwell people of any age or either sex.

The average physical educationist, and some of them are medical men it must be said, see no other cause for "short-windedness" than insufficient chest capacity and weak pectoral muscles. The heart is practically ignored as a cause of dyspnœa. All advice tends to the development of the chest girth and chest capacity. The patient must learn to blow better and must get larger pectorals. This is the cure (?) and if it does not succeed, the case is usually considered insurmountable.

Again, no difference seems to be made by anybody as to the intra-thoracic pressure during different exercises. It has lately become the fashion to incline toward athleticism. In fact there are "schools" or "systems" of athletics. Some of these are —well, absurd. The motives of the originators I believe to be honest, but the effects are detrimental. One such system favored by a growing number, and undoubtedly good if properly used, is that which is so simply and perspicuously outlined by Mr. Blakie in his little school manual. Its principle is very light work, slow movements and intermediate rests, associated with long, slow, and deep breaths that are held for several seconds. It is against the indiscriminate use of these that I would raise a warning cry.

Some of these "mild" (?) exercises cause not only an enormous increase of the intra-thoracic pressure, but also of the pressure in the veins of the head and neck. The danger is evident. It may affect the heart, but of this in another note. It may affect the lungs beneficially or detrimentally; beneficially if it is desirable to force the air into all parts of the alveoli and cells under considerably increased pressure, and detrimentally under other circumstances as tending to pulmonary anæmia, atrophy of the alveolar walls and eventually emphysema. It may cause a rupture of the vessels of the inside or outside of the head, but especially of those small delicate ones of the brain that are found within the internal capsule. I could mention instances where I feel certain that lives were lost because of well meant, but wrong and carelessly given, advice about exercise, while others are now ebbing away at a quicker rate than was indicated previous to the beginning of gymnastics.

A remedy that so taxes the powers and is so potent for good should be most carefully employed. Many consider the lighter gymnastic performances innocent, but a personal trial by one who is weak and follows instructions to the letter will develop the fact that the remedy is often heroic.

The author of a recent book on this subject, and he is not a physician with a degree, describes a certain exercise for "broadening the chest,"[1] which has little or no effect whatever on the chest capacity, but increases the girth of the chest only by enlarging certain muscles, besides increasing the size of the ribs at the site of muscular attachments. He figures upon the contraction of the pectoralis major in this movement and so far he is right, but he forgets that other muscles take part in the work, one of the most important being the serratus magnus, which antagonizes the pectoralis major, in the exercise advocated, by pulling downward and backward upon the ribs while the

[1] This motion is done with the pulley weights. The back is toward the machine and the hands are held above the head. They are then brought downward, forward, and inward to a point on the median line, a little below the pelvis.

other pulls upward and backward. The serratus acts to hold the shoulder forward in this exercise. A deep breath is taken before the motion is begun and the consequence is that the imprisoned air is compressed, the pulmonary circulation is impeded, and the nourishment of the lungs diminishes for the time being. Sometimes this may be desirable and at other times not. Only a competent physician can judge which is requisite.

I would lay down as a safe rule that *very few exercises expand the chest that call into direct action the pectoralis major muscles.* All such tend to compress the chest. Actual measurement with the calipers and tape demonstrates this to be a fact.

Another movement with the pulley-weight, illustrated by Fig. 1, in which the arms are brought forward with the elbows extended, while the back is toward the machine, causes a strong direct contraction of the pectorals, and is generally said to expand the chest; but, instead, it compresses the chest.

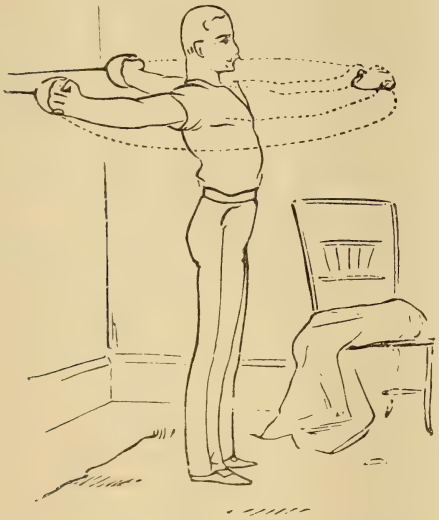

Fig. 1.

Fig. 1 compresses the chest, but exercises principally the pectoralis major or great chest-muscle of each side. This leads to a marked increase in the size of the chest-muscles and outside girth of chest, and is a good preliminary for those learning to dip.

Dipping is also considered a good exercise for causing chest expansion, but it, too, compresses. The same is true of all exercises that forcibly contract the pectorals and cause a movement of the arm. Contract these muscles, though, while the arms are firmly fixed forward, and it is, of course, evident that there is a greater tendency to chest expansion than when the arms move; hence the attitude of the asthmatic, with arms braced forward on a window-sill during a paroxysm.

The exercises that have thus far been enumerated are generally said to be respiratory, but really are chest-compressing exercises. The following are a few that are truly respiratory. By that I mean such as cause an expansion of the chest and a diminished intra-thoracic pressure, thus causing an active and almost irresistible inspiration. Such are the movements shown in the following figures:

In the instance of Fig. 2, the lower part of the chest is forced out very appreciably, the expansion involving the entire chest up to the clavicles. With the hands held at full reach above the head by the pulley-weight,

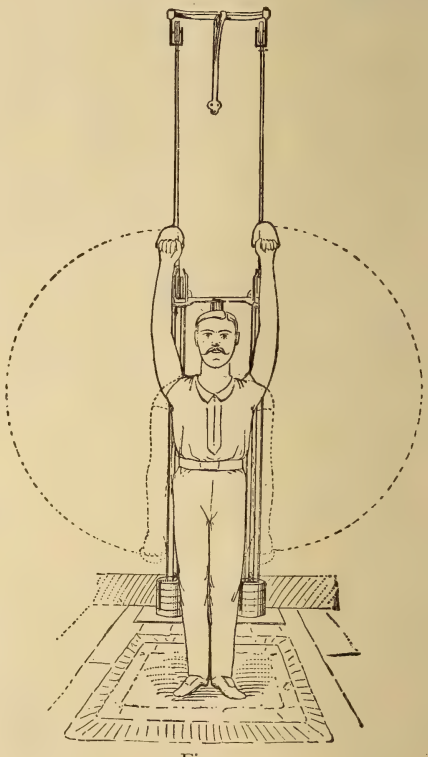

Fig. 2.

and without any effort by the patient, a long deep breath just before the exercise comes as natural, and is as pleasant, as the enjoyable morning stretch upon rising; then the arms are brought down slowly to the sides of the thighs, while the air remains in the lungs. The quickness of the movement should depend largely upon the temperament and condition of the patient. Expiration may take place at the end of the downward movement.

Fig. 2 exercises the front and back of the deltoid, pectoralis major, latissimus dorsi, teres major, and serratus magnus.

This motion strengthens the front and back arm-pit muscles and the chest-muscles, besides expanding the chest, causing it to flare out at its lower part—a good movement for narrow-chested persons and those desiring to become "long-winded" for long-distance running. The elbow must be kept stiff, while the downward motion should be accompanied by a deep inspiration and the upward movement by expiration. It is one of the very best respiratory exercises.

The exercise shown in Fig. 3 increases to a remarkable degree the antero-posterior diameter of the chest. The same motion in a standing posture would partly compress the chest, because of the counteraction of the serratus magnus in keeping the scapula, shoulder, and upper end of the humerus forward. Resting the back upon the floor dispenses with the action of the serratus magnus, and hence the difference in the effect of the same exercise done under changed conditions.

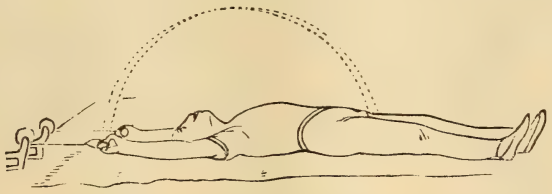

Fig. 3.

Fig. 3 exercises the biceps slightly, belly, pectoralis major, lattissimus dorsi, deltoid, teres major, rhomboidii, and trapezius.

The front of the upper arm, the belly, front of the chest, side of the back, the shoulder, back of arm-pit, and the upper part of the back. One of the very best motions for increasing the depth of the chest. As the arms come up, with the elbows stiff, the chest is seen to rise until it reaches its limit of expansion. This, with the motions shown in Figs. 4 and 2, constitute a fine combination of exercises for expanding the chest.

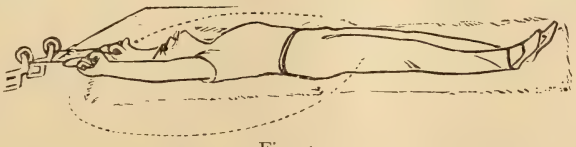

Fig. 4.

Fig. 4 exercises the biceps slightly, pectoralis major, lattissimus dorsi, teres major, and trapezius.

The front of the upper arm, the front of the chest, the side of the back, back of the arm-pit, and the upper part of the back. This is essentially the same as Fig. 2, except that it is somewhat easier, and the hand, being on the ground, insures a steady motion of the two sides on the same plane. It is a good exercise, if one begins to feel tired, or for those who are too weak to do it standing, as in Fig. 2.

Fig. 4 shows a movement essentially the same as that shown by Fig. 2, but is better for weak patients, as they then exercise only those muscles necessary to inspiration and expansion, and avoid the tiring effects of using the other necessary muscles while standing.

In conclusion, then, of the so-called respiratory exercises, some expand and others compress the chest. It may be desirable sometimes to produce one of these effects and at other times the other effect. Both have their uses, especially in supplementing the pneumatic cabinet. Will Drs. Herbert F. Williams and Benjamin F. Westbrook, of Brooklyn, work up this suggestion in connection with their cabinet patients? For increasing the intra-thoracic pressure, employ, for instance, the exercises shown in Fig. 1, and to diminish this pressure employ those shown in Figs. 2, 3, and 4.

The movements for changing the intra-thoracic pressure may be multiplied, but to state these is not my object at present. This note serves mainly to point a way. Details must be left to circumstances, as, for instance, mechanical facilities for exercise (apparatus, etc.), anatomical knowledge of the prescribing physician, and his mechanical ingenuity. Care must be taken to begin gradually and with very light work. It takes but little work to cause soreness the next day, and this must be carefully avoided in sick and feeble persons.

It must not be forgotten—as is so commonly done—that chest-girth is no reliable index of lung capacity, because large pectorals, especially while contracted, make a difference of several inches as compared with the girth of a chest just as large in a person with very thin and flabby pectorals; in fact, I have satisfied myself in several instances that increased girth of chest was accompanied by actual contraction of the chest itself. In these instances, the increase was due to muscular development.

My next paper will deal with the heart in relation to "shortness of breath," and the remedy.

CORNEAL TRANSPLANTATION.

BY L. WEBSTER FOX., M.D.,
OPHTHALMIC SURGEON, GERMANTOWN HOSPITAL, PHILADELPHIA, ETC., ETC.

In engrafting the cornea of the rabbit into that of the living subject with preservation of transparency of corneal tissue, Professor Von Hippel has achieved results little dreamed of by Deiffenbach, who in 1824 first experimented unsuccessfully in transplanting sections of cornea in rabbits. In THE MEDICAL AND SURGICAL REPORTER, October 11, 1887, a letter is published in which the writer gives the details of Von Hippel's now celebrated operation, having had the opportunity of making a thorough examination of his patient nearly a year after he performed the operation. Without going into a history of keratoplasty, which has been exhaustively reviewed by Dr. August Wagermann, of Göttingen, in *Graefe's Archives*, vol. XXXIV, bd. 1, 1888, I will at once give the history of a case, the details of the operation, and the result of that operation.

Mrs. Mathilda Schick, age nineteen, of 474 North Fourth Street, Philadelphia, came under my observation in January of this year, suffering with opacities of both corneæ: sequelæ of a pronounced keratitis. In the right eye, the parenchymatous opacities extended throughout the entire corneal tissue to within one mm. of the corneo-scleral margin—its greatest density being in the centre opposite the pupil. Vision, *nil;* light perception and projection good, but movements of the hand not recognized. The left eye was in like manner affected, but the corneal infiltration was not so dense, nor as extended. The vision in this eye was practically useless.

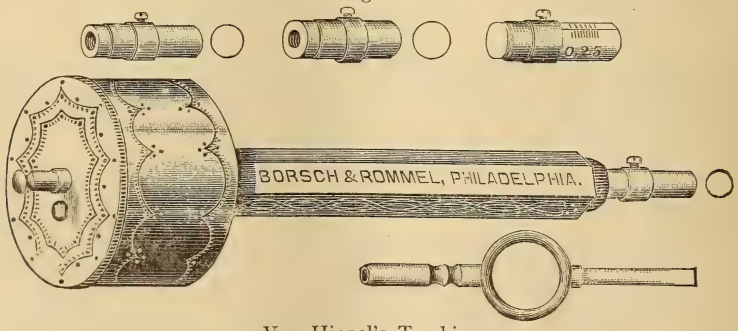
The general history of the case prior to the attack of keratitis which resulted in the loss of vision is irrelevant; she enjoyed good health, and was free from hereditary taint.

DETAILS OF THE OPERATION:

Anticipating a major operation on an eye, the patient is placed on preliminary treatment, which consists of doses of hydrarg. bichlorid. just beyond its tonic effect. The nasal passages are examined, and antiseptic precautions are always instituted.

Professor Von Hippel's trephine is a very simple but ingenious instrument. The trephine is driven by a spring which is allowed to escape by gently pressing a small button placed in a convenient position on the top of the case enclosing the spring movement. The trephine is screwed to a bar which is attached to the spring lever—this is enclosed. The circular knife or trephine has its cutting edge guarded by a circular band or collar which graduates its cutting depth. The spring is wound by a key.

Fig. 1.



Von Hippel's Trephine.

The eye of the patient is thoroughly cocainized, and the eyelids separated with an ophthalmostat. The cutting edge of the trephine is then brought in juxtaposition

with the cornea, perpendicular to its plane, the button on the top of the instrument touched, allowing the escapement of the spring which drives the trephine, making a circular incision to the necessary depth. After the circular incision is made, comes the most important step in the operation, *i.e.*, the dissection of the leucomatous tissue from the membrane of Descemet. This is done by grasping the inner lip of the incised tissue with a delicate forceps, then with great care and delicacy of touch removing the obstructing tissue. A knife shaped after Beer's model was the best instrument which suggested itself after many trials in preliminary experiments.

The rabbit selected from which to obtain the graft is usually about six months old. Von Hippel usually selects a doe. The eye of the rabbit, which is now under cocaine, is thoroughly washed with an antiseptic fluid, the eyelids separated by a speculum, and the eye-ball drawn forward by an assistant. Two strabismus-hooks, inserted under the superior and inferior recti muscles, answer best. By

Fig. 2.

1. Graft. 2. Cornea.

drawing the globe forward, the trephine may be guarded more carefully in its incision, which is made through cornea and Descemet's membrane. The graft is then inserted in the cornea of the patient, being pushed into place by a delicate wire probe passing through the trephine. After the graft is fixed firmly in place, the upper eyelid is drawn forward and downward, all being securely held in place by a pressure bandage, delicately adjusted. After three days, the bandages are removed and the eye examined.

In the case now reported, the graft was slightly hazy at this time, which Von Hippel finds to be the rule; while, if the edges of the graft have remained in place, growth will take place.

From day to day, the eye was carefully examined. After the sixth day, there was no change in the slightly hazy condition of the graft; but, as anticipated, the cornea surrounding the graft from the first day of examination (third after the operation) took upon itself healthy inflammation, thereby giving nourishment to the graft. Very little pain followed the operation, and at no subsequent time was it found necessary to give an opiate. There was no rise in temperature. The process of healing was uninterrupted.

But once up to present writing has there been any untoward symptom—then, owing to a nervous shock, a sudden keratitis developed, which was promptly checked by antiphlogistic measures administered by my friend, Dr. Heyl, who was called in consultation by my assistant, Dr. Motter, during my absence from the city at that time.

The operation was performed at the Germantown Hospital, April 29, 1888, in presence of the hospital staff.

At present writing, July 2, the case presents the following conditions. Right eye: Union of graft perfect, its integrity preserved, and covered with corneal epithelium; transparency of graft progressing—central vision increased to counting fingers to four

Fig. 3.

1. Descemet's membrane. 2. Cornea.

feet; able to attend to personal wants and go about alone in safety; color-perception keen. The restoration of transparency in the graft has not been general, but stellate, *i.e.*, certain segments began clearing; the centre of the graft is the last to show improvement. In looking across the apex of the cornea, one is able to look into the transplanted tissue, proving a clearing down to the middle layers of the graft. If this process of change continue—and we have every reason to believe it will—we shall have the same result that Von Hippel obtained. The cornea surrounding the graft has recently begun to clear, which may become more and more extended, leaving only a narrow circle of connective tissue between graft and cornea.

To Drs. Kimmell and Cameron, house surgeons at the hospital, I am indebted for their valuable assistance at the operation, and the subsequent attention they gave the patient in carrying out the tedious details of the after-treatment.

In the *Ophthalmic Review* for June, just received, I find Priestley Smith publishes an abstract of the article of Wagermann mentioned above. To physicians who are not conversant with the German language, and who wish to obtain the fullest and clearest description of Von Hippel's experiments yet published, I would recommend the abstract of Priestley.

1304 Walnut St.

TREATMENT OF SNAKE-BITES.

BY WILLIAM R. D. BLACKWOOD, M.D.,
PHILADELPHIA.

In an editorial in the REPORTER for June 9, reference is made to the treatment by alcohol of snake-bites, in which it is stated that "profound and continued intoxication" was instituted in a New York hospital, and reference was also made to the use of permanganate of potassium in the lesion considered. During my service in the army after the war—and in two cases during the war—I had an unusual number of snake-bites to treat, and I have further hunted up all available records upon which reliance could safely be placed. The result of my studies is that alcohol *is* a certain antidote, and that the so-called chemical antidotes are of *no service whatever!* Of all remedies, the permanganate appears to be the poorest. I believe it criminal to trifle with life when a rattlesnake or a cotton-mouth has done the business for the patient, for the administration of either that or ammonia simply wastes valuable time. Everything depends on getting the patient under the influence of alcohol at the earliest possible moment, but intoxication *is to be avoided* in my opinion.

In my own cases, the pulse was the guide—when it flagged, alcohol was given in a dose sufficient to bring it up, and, the sooner the case was taken in hand, the less the dose. I generally used "apple-jack," because in Alabama and Georgia, where most of the cases occurred, that beverage was most readily accessible; and it was, moreover, a better article than new whiskey, which, not being rectified or tinkered with *secundum artem* by the trade, contained too much fusel oil to be good for the patient in his convalescence. In saying this, I do not mean that he had to go through the usual nausea and headache succeeding a debauch, for in my cases the sufferer could not, in strict language, be said to be drunk at any time; but those physicians who know the effect of large doses of raw corn whiskey can testify to the wretched disturbance of the nervous system due to the amylic alcohol therein contained. I was at a loss, for a time, in accounting for the frequent convulsions amongst soldiers during the reconstruction era, in those who went on sprees after pay-day, until I detected the nature of the liquor consumed. It is essential, therefore, that good whiskey be used.

Another point is the reference to Dr. Mitchell's opinion that "seven-eighths of all persons bitten by rattlesnakes recover." If he means that the percentage of dangerous bites runs in that ratio without treatment, he had better not get bitten himself. From what I know of the subject—and I have collected a large number of presumably authentic reports—I believe that, aside from thorough treatment by alcohol, seven-eighths of all cases bitten by the *crotalus horridus* of over three years old will *die*, and the *toxicophis piscivorous* is worse, for its bite is fatal at an earlier age. I know of a case in which a cotton-mouth two years old killed a man who had energetic treatment by permanganate, ammonia, caustics, cupping over the wound, and split-chicken poultices. The doctor who reported the instance to me was a tee-totaler, which was a bad thing for the patient.

Most snakes with us are non-poisonous, and the rustling of the grass, &c., under the escape of the reptile after its attack is taken for the music of a rattler by the frightened victim or onlookers. Of course, many escape thus, and the results of experiments in the laboratory on rabbits possess no value whatever concerning man's relation to snake-bites. I have, in a paper entitled "As to Snake-bites," in the *Medical Register* of March 24 last, more fully stated my views on this subject; but, to avail myself of the large circulation of the REPORTER, I write, hoping to enlist the good sense of those who are called on to treat snake-bites by going at the matter promptly and decidedly. Don't "proceed to operate" or "exhibit" an antidote—GIVE the patient alcohol in some form in plenty, but don't make him drunk unless you can't help it.

246 North Twentieth Street.

—Dr. Thomas J. Mays has been selected to deliver the address before the Lehigh Valley Medical Association at its next annual meeting, at the Paxinosa Inn, Easton, Pa., August 15, 1888. His subject will be: "The Treatment of Lung Cavities."

PROFESSIONAL PREJUDICE.[1]

By RICHARD J. LEVIS, M.D.,
PHILADELPHIA.

Prejudice has done more to maintain and perpetuate error than any other cause.

Prejudice has been defined as a notion or opinion which the mind entertains without knowing the grounds and reason of it, and which is assented to without examination. There was a time in the past when we were obliged to rely on foreign surgical books, but the development of American surgical works is so satisfactory, and the future of American surgical literature seems so assured, that it is entitled to our almost exclusive patronage. American surgical literature has made its impress on the entire surgical world.

Our systematic works on surgery are not exceeded in merit for general adoption as the leading text-books for all of our medical schools. With the excellent works on special departments, as gynecic, ophthalmic, and oral surgery, and the monographs on fractures and dislocations and genito-urinary surgery, we would not suffer nor fall behind if nothing on these subjects were ever brought from abroad. Still we erroneously encourage the reprinting of English books, and it continues to be a paying business to publishers. The absence of copyright enables them to publish unfairly without compensation to foreign authors, and thus they can undersell the works for which Americans are paid. In disregard of a sense of right and justice to the profession and to the community, this traditional error continues.

We are now possessed of such meritorious text-books of general surgery that it is no longer necessary that our medical colleges should recommend works of foreign origin. But this is done to a great extent, and quite frequently it is evident that a marked prominence or preference is given to the foreign text-books. I have examined the annual announcements of seventy-two American regular medical colleges, and find that there are in all one hundred and fifty-seven recommendations of American works and one hundred and eighty-six of foreign authorship. The single well-known surgical text-book receiving the greatest number of faculty recommendations is of English origin.

The inference from this traditional error of preference for foreign works must be the conclusion that many of the faculties of the schools are influenced by either an honest conviction of the inferior character of the works of American origin, or else by a spirit of dishonorable jealousy of our own countrymen, of high renown as authors, or of the colleges with which some of them are associated.

The science of surgery is based on ascertained truths, and we need less of theories and systems—not what is thought or supposed, but what is observed and found to be fact. Much error is transmitted and becomes traditional from the lack of systematic records of observation in hospitals and by private practitioners. It is but recently that some of the largest general hospitals of the country have begun even the most simple records of surgical cases. The recording is usually done by the resident surgeons, who are young and inexperienced, and the records receive little, if any, supervision from the attending surgeons, who are chief in authority in the wards. From the hundreds of thousands of patients admitted to the various hospitals of our country, the results to surgical literature by records from practical experience are extremely meagre. The records of the experience of individual practitioners, of intelligent and trained minds, would be a gain to surgical progress, and tend to avoid the transmission of traditional errors. From practitioners in regions far away from medical centres, in such locations as are abroad styled provincial, have originated some of the most valuable practical discoveries and advances. There may be instanced the discovery of vaccination, in rural England, by Jenner; the origin of ovariotomy, by McDowell, in what was then a frontier region of Kentucky, and its development by Atlee, in Lancaster County, Pennsylvania; and the very beginning of practical gynecology, by Marion Sims, in the obscurity of Northern Alabama. It is said that the ploughman, tilling the fields of the western slope of our continent, who keeps his eyes intently on the furrow, may occasionally find nuggets of gold; and so the faithful toiler amidst human ills is liable to unearth jewels of fact, which, garnered and recorded, will add to the wealth of surgical knowledge.

Few of the advances of civilization have been made without meeting the obstacle and opposition of prejudice. The early histories of Harvey, Jenner, Morton, and Lister are the records of struggles and suffering under professional contumely and vicious opposition. Dr. Morton, to whom the world is

[1] Extract from the Presidential Address, on The Traditional Errors of Surgery, at Thirty-ninth Session of the Medical Society of the State of Pennsylvania.

indebted for practical anæsthesia, went early from this life, without either proper award of honor due him or even reimbursement for the outlay of his entire fortune by time and labor spent in introducing his discovery. Practical anæsthesia commenced with its production by Morton with sulphuric ether. It was a more original discovery than was vaccination by Jenner, who admitted that he had learned from the country people that those who had become accidentally inoculated with virus from the cow were thereby rendered secure from smallpox. Time, which "at last sets all things even," will write on an immortal tablet the name of Morton: "Death opens the gate of fame, and shuts the gate of envy after it."

As an illustration of the spirit of prejudice against Morton's introduction of anæsthesia by sulphuric ether, and of its slow adoption by surgeons, I quote from the *Medical Examiner*, of this city, in the year 1846:

"We should not consider it entitled to the least notice, but that we perceive, by the *Boston Medical and Surgical Journal*, that prominent members of the profession in that city have been caught in its meshes. We are persuaded that the surgeons of Philadelphia will not be seduced from the high professional path of duty into the quagmire of quackery by this will-o'-the-wisp. We cannot close these remarks without again expressing our deep mortification and regret that the eminent men who have so long adorned the profession in Boston should have consented for a moment to set so bad an example to their younger brethren, as we conceive them to have done in this instance. If such things are to be sanctioned by the profession, there is little need of reform-conventions or any other efforts to elevate the professional character. Physicians and quacks will soon constitute one fraternity."

The editor of *The Annalist* said:

"The last special wonder has already arrived at the natural term of its existence, and the interest created by its first advent has, in a great measure, subsided. It has descended to the bottom of that great abyss which has already engulphed so many of its predecessor novelties, but which continues, alas! to gape, until a humbug yet more prime shall be thrown into it."

The New York Journal of Medicine said:

"We are sorry to see many of our brethren, at home and abroad, stooping from the exalted position they occupy in the profession to hold intercourse with, and become the abettors of, quackery in any form. Such doings are certainly contrary to the ethics of the profession, and should not be tolerated for a moment in any one."

The Medical and Surgical Journal, of New Orleans, offered the following sentiment:

"That the leading surgeons of Boston could be captivated by *such an invention as this*, heralded to the world under such auspices and upon *such* evidences of utility and safety as are presented by Dr. Bigelow, excites our amazement. Why, *mesmerism*, which is repudiated by the *savans* of Boston, has done a thousand times greater wonders, and without any of the dangers here threatened."

Such extracts illustrate definition of prejudice. The animus was not that of "honest doubt," but of vicious opposition and jealousy. "But even the right comes uppermost," and as early as 1847 Oliver Wendell Holmes, who created the word anæsthesia, wrote:

"Nature herself is working out the primal curse which doomed the tenderest of her creatures to the sharpest of her trials, but the fierce extremity of suffering has been steeped in the waters of forgetfulness, and the deepest furrow in the knotted brow of agony has been smoothed forever."

There is no sadder or more painful story of traditional error, due, for the most part, to obstinately held preconceived opinions, than that of the opposition to and the long probationary trial of ovariotomy.

The practical establishment of ovariotomy is due to one of my honored predecessors in this Presidency, Dr. John L. Atlee, of Lancaster, seconded by his younger brother, Dr. Washington L. Atlee, of this city.

The single precedent of McDowell probably had little, if any, influence on these pioneer surgeons, who, by long-continued patient labor, bearing the brunt of professional opposition and obloquy, demonstrated the value of the operation. The early triumph of ovariotomy is due to the labors, trials, and sufferings of the Atlee brothers.

In an address by Dr. Washington L. Atlee, about thirteen years ago, he said:

"As, during the probationary stage of ovariotomy, I was under the ban of the profession and had to suffer from unjust obloquy, I hope that I may be pardoned in any honest manifestations of triumph since the curse has been removed."

. . . . "Ovariotomy was everywhere decried. It was denounced by the general profession, in the medical societies, in all the medical colleges, and even discouraged by the majority of my own colleagues. I was misrepresented before the medical public, and was pointed at as a dangerous man, even as a murderer. The opposition went so far that a celebrated professor—a popular teacher and captivating writer—in his published lectures invoked the law to arrest me in the performance of this operation."

. . . . "What is most remarkable, the strongest opposition came from those who had never seen the operation, who would not consent to see it, and who consequently knew nothing about it."

"At the opening of the session, 1844–'45, of Jefferson Medical College, Professor Thomas D. Mütter, in his introductory address, used these expressive words: 'A distinguished philosopher has classed man among the most cruel of all animals. . . . . Certain it is that some of our operations may be considered as supporting, to a limited degree, the charge made against our race; and there is none in the whole domain of surgery better calculated to

elicit, even among the profession, a more profound sensation of horror, or better deserves the epithet of cruel, than one recently introduced into practice; and, were we not convinced that nothing but a fervent desire to relieve a suffering mortal could induce a surgeon to undertake its performance, we should at once look upon its author as a being destitute of either sympathy or compassion, and richly deserving the detestation of his fellow-men. The operation to which I refer is that for the removal of ovarian tumors!'"

. . . . "Professor Charles D. Meigs thus emphatically expressed himself: 'I detest all abdominal surgery.' 'I am free to say that I look upon all operations for the extirpation of the diseased ovary as not to be justified by the most fortunate issue in any ratio whatever of the cases.' 'Dr. Atlee's coolness in cutting open a woman's belly does not, I think, entitle him to judge more clearly than I, as to the morals of such surgery. . . Dr. Atlee likes ovarian operations; on the contrary, I detest them, and should be glad to see them prevented by statute.'

. . . . I should be glad if you would look over the statistics of ovariotomy to discover how many bellies have been ripped up by the surgeons in the expectation of having the blessed satisfaction and *praise* of curing a tumor. Suppose a surgeon to open a woman's belly to extirpate an ovary; that he finds no ovary there; that he then sews up the gash; and next, that she dies! What should the attorney-general say? 'It would scarcely be unfair to say, of all the fatal results of operation for extirpation of the ovary, that the patient is compelled to render her soul to God, and her carcass to the surgeon.'"

We have, in the soulful devotion of the Atlee brothers to ovariotomy, the material of a homily, with the text from Solomon: "Love is strong as death; jealousy is cruel as the grave."

I cannot conclude this sad subject of the struggles and triumphs of ovariotomy better than by again quoting Dr. Washington L. Atlee's own words:

"The history affords a moral to all young men who are cultivating the fields of science and humanity. In all the battles of professional life, let them weigh well their foundation of action, think for themselves rather than follow doubtful authority, cultivate a pure conscience, adhere strictly to professional and moral rectitude, sacrifice self on the altar of humanity, allow no personal considerations to outweigh their obligations to their patients, and turn neither to the right nor to the left, while in the path of duty, when professional storms assail them. Then, even should they err at times, they will pass through the fire purified, though the whole world may have been armed against them."

—The *Weekly Abstract of Sanitary Reports*, July 13, 1888, says that the following information was received from Plant City, Florida, under date of July 10: "Only about thirty persons in the place who have not had fever. Five new cases reported to-day. Total population, 200. Most of the unacclimated move out. Guard around place to prevent communication."

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION IN PÆDIATRICS.

Stated Meeting, June 27, 1888.

J. Lewis Smith, M.D., Chairman.

Before introducing the essayists of the evening, the Chairman stated that the importance of the subject which they would discuss was made evident by the number of deaths (two thousand) which took place annually from summer diarrhœa in New York City. It was the dreaded disease of the hot months.

Dr. A. Jacobi then read his paper, entitled

Remarks on Summer Complaint,

which were directed more especially toward defining the term. He regarded summer complaint as a clinical entity, so to speak, and not a pathological entity. He made that point because, he said, it had become the custom to so shape our ideas regarding the pathology of this disease, and indeed of diseases generally, as to assume that there was but one cause for a large number of maladies. But this, from the clinical standpoint, he thought, was decidedly wrong. The very fact that a large number of bacteria had been discovered, and that a few diseases had been traced to a single bacterium, had led to the assumption that nearly all infectious diseases, and some others, are due to such a cause. This assumption he regarded as probably true in many cases, and it was desirable that it should be so; but he thought physicians had drifted too far with that current. We were inclined, he said, to believe that such diseases as diphtheria, scarlet fever, and so on, are due to invasion of the system by certain bacteria. He said 'we were inclined to believe it,' but it has not yet been proved; yet it was possible, it was probable, it was even desirable. It would facilitate the study of pathology a great deal, if it were proved. But imagine, he said, one asserting that there could be no inflammatory disease of the respiratory organs without a pneumococcus; that pneumonia, under all circumstances, meant a coccus disease. This would certainly be a mistake. The same, he thought, is true of summer complaint. Different forms of inflammation and ulcerations in the intestinal tract give rise to the same clinical symptoms. While it is true there is a form of intestinal inflammation which appears to be due to the

formation of bacteria, yet, when speaking of summer complaint, physicians often have in mind a number of diseases which have the same symptoms; symptoms which do not belong to one and the same anatomical lesion.

A question which is constantly recurring is: whether or not heat by itself is a sufficient cause of diarrhœa. This direct effect of heat had been denied before the Academy only a short time ago by Dr. Seibert, and the questions of fermentation and bacteria had come to monopolize attention to such an extent as to exclude from vision any other etiological factor.

Dr. Jacobi holds that diarrhœa may be produced by the influence of heat alone, and thinks that not unfrequently such cases are among the most severe. Diarrhœa sometimes occurs during sunstroke in the adult. Why solar heat should act on the brain alone, and not on other parts of the nervous system, he regarded as inexplicable. Infants brought up on good mother's-milk should never, according to the bacterial theory, have diarrhœa, yet we know that heat affects them in the following ways: it produces convulsions; it produces convulsions and diarrhœa; it produces diarrhœa. At any age, diarrhœa from neurotic causes is frequent enough. It can be produced by dividing the mesenteric nerve. The center for this paralytic diarrhœa is, he thinks, in the medulla oblongata.

Dietetic Management of the Summer Diarrhœa of Infants.

Dr. A. V. Meigs, of Philadelphia, read a paper on this subject. He first described what he regarded as proper dietetic management of the complaint, and then gave his reasons for it. When called upon to treat a case, the first question which the physician should ask is: What food has the child been taking? If it is being nursed, the physician should be very careful about ordering a change; it should be done only in case he is convinced that the diet is the cause of the complaint. Even in cases of acute cholera infantum, he could hardly convince himself that it was well to take the infant from the breast if it was previously healthy and the mother's health was also good.

The child becomes thirsty, and should be given water. If this is given instead of milk between the stated periods for feeding, the system would receive what it needed and nothing more. He thought stimulants were more nearly allied to dietetics than to therapeutics, and would say that he regarded stimulation as important in cases of summer diarrhœa. A teaspoonful of brandy might be put into a glass of drinking-water, or the child might receive thirty drops in sweetened water every two hours.

If the mother's milk is in any way faulty, nursing must at once be stopped. In some cases, half an ounce of beef-juice with a pinch of salt will be of benefit. But the best food for infants, after the mother's milk, is cow's milk, and the question of artificial feeding in health and in disease hinged, he said, largely on its method of use. He was unable to accept the view that the best treatment of summer diarrhœa and acute cholera infantum is to stop all milk and put the child on meat-broths. Cow's milk contains too much caseine and must be diluted; it did not contain a sufficient amount of sugar, and must be sweetened; it was acid, and had to be rendered alkaline; when diluted, it should have an additional amount of the fatty elements added. The milk should be absolutely untainted when used. By clinical experience he had found that cow's milk to which had been added cream, sugar, and lime-water, gave good results; and, when by chemical analysis he had found that such a mixture contains the same constituents in almost exactly the same proportion as human milk, he had become entirely convinced of the value of this food. Since writing his book, he has further studied the subject, and has settled upon the following method of preparing the milk: he takes one quart of cow's milk, puts it into a tall narrow pitcher; after it had stood three hours, the upper pint is poured off. This contains the greater part of the fat, the cream. When the child is to be fed, he mixes together two ounces of this, three of lime-water, and three of sugar-water. If the infant is quite young, only two to four ounces will be needed at each feeding, and only that much should be prepared. The general directions, he said, are the same as for feeding a healthy child. In infants in health, it is very important to take a lesson from nature, and not increase the strength of the food before the sixth month or twelfth month, and in cases of summer diarrhœa this is absolutely essential. While he regards this as in most cases the best food, he varies it in many ways to meet the needs of different cases. Of the four things necessary to make cow's milk suitable for children with diarrhœa, addition of cream, sugar, and lime-water, the least essential probably is the use of milk-sugar. Occasionally it becomes advisable to use cane-sugar in diarrhœa. The

addition of some starchy material, he thinks, is of great advantage in many cases. One of the best is arrowroot; and the old method of boiling flour in a sack, he says, is excellent. Dr. Meigs recommended Mellin's food, which should be given in the proportion of a teaspoonful to four ounces of whatever milk food is being used. In some cases, excellent results had been obtained by taking away all milk and administering animal broths alone, although in his experience this is only exceptionally the case. Children commonly soon refuse their food, if given broths alone.

He regards it as very important to give particular directions as to how often the infant should be fed and the quantity of food to be taken. He believes the best results are obtained by not making much change in the frequency of feeding in mild cases; for young infants, feed every two or three hours, and, for those of six months, feed five or six times in the twenty-four hours. In severe cases, on the contrary, his rule is to give a small quantity of food, half an ounce to three ounces, every two hours. If the case is critical, collapse threatening, stimulants will be more to the purpose. One should not change the food too soon because the patient fails to grow better immediately.

Dr. Meigs thought the time was not yet ripe for unqualified acceptance of the action of bacteria or chemical poisons in the causation of all cases of summer diarrhœa, and of basing the treatment and feeding on this view alone. There are too many reasons, he said, some of them strong ones, pointing the other way. Especially should the physician not permit this view to lead to the substitution of an exclusively animal diet in every case.

A Clinical Study of the Etiology and Treatment of the Summer Diarrhœa of Infants.

Dr. Simon Baruch read a paper with this title. He believes now that the summer diarrhœa of infants is due chiefly, though not solely, to the influence of micro-organisms. Certainly the theories heretofore held regarding its etiology are faulty. Unsanitary conditions, artificial feeding, and over-heat can not now be regarded as more than predisposing elements. He had found summer diarrhœa as fatal in the pine forests of Georgia as in the tenements of New York. That the disease is not due alone to artificial feeding, he thought was proved by the fact that very few children died of diarrhœa in the winter, although they were then fed the same as in the summer. High atmospheric temperature, he said, doubtless exercised an important influence in the production of summer diarrhœa. While unsanitary conditions, artificial feeding, and excessive heat act in unison in the production of summer diarrhœa, yet he believes their *modus operandi* is generally misunderstood. He said he was convinced that the kind of food would be of less importance if we could prevent the entrance of micro-organisms into its preparation. Human milk he regards as the best, and largely because when taken it is free from unwholesome conditions. Cow's milk is next best, and it should be kept as clean as possible. He suggested that the goat might be tamed from the earliest months, so that by some mechanical device the babe might draw its milk directly from the teat. In order to sterilize milk with heat, it must be boiled under pressure; raising it to a temperature of 212° F., he said, would not effect the purpose.

Dr. Baruch next discussed the hygienic management of the patient, and dwelt somewhat on the advantage to be derived from sponging the body, and from the use of cold water to reduce temperature. The external surface might be clammy and cold to the touch, yet in such cases, he said, it would often be found that the temperature, when taken in the rectum, is considerably elevated, perhaps even to 106°, and the cold bath would be of benefit. He thinks it advisable to cleanse the infant's mouth with a solution of boracic acid. The nipple should be kept clean.

In the treatment, he sought to remove or diminish the bacterial supply, to neutralize their effect, to remove them from the alimentary tract, to meet the exhaustion and other effects of the diarrhœa. Regarding an exclusively meat diet, he said he was not aware that there are any number of physicians who are accustomed to order it. He did not think it necessary, at least for a longer time than a day. He usually gave it with something else. Much benefit will often be derived from total abstention from food for a few hours. He employs with benefit washing out the bowel through a rubber tube. If the patient lies on its belly across the nurse's lap, overdistention will be obviated. He said he did not expect any decided results from the internal administration of antiseptics. He now has little confidence in astringents, which he formerly used extensively. After all materials had been removed from the intestinal tract,

he regarded opium as of benefit in allaying irritation, but hitherto it had been used too indiscriminately. Alcoholics, he thinks, are a valuable aid.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, June 13, 1888.

The President, J. Solis-Cohen, M.D., in the Chair.

Dr. J. H. W. Chestnut read the

Report of a Case of Ovariotomy.

Under the benign influence of antiseptics, the recent progress of abdominal surgery has been so remarkable, and the number of ovariotomies has been so considerable, that this case is reported, not because of special characteristics, but rather as a further demonstration or exemplification that the operation in question has been removed from the border-land of doubt, and has become one of those which the general practitioner who does surgical work may, under proper circumstances, essay to perform.

On November 10, 1887, Mrs. J., æt. thirty-seven years—a small woman, weighing one hundred pounds; the mother of two children, the younger six years old—consulted me in reference to an abdominal enlargement which occasioned her uneasiness. Her periodical sickness was regular but scanty. She had nausea, and was much distressed by frequent, and at times ineffectual, efforts at micturition.

A careful examination of her abdomen by palpation revealed a tumor about the size of a large apple, which inclined from the left to the middle and seemed to be solid. A vaginal examination gave a movable womb, a firm os and conjoined manipulation assured me that the case was not one of pregnancy. The uterine sound was used and gave a measurement of 2.7.

Under the impression that the nausea and irritation of the bladder were due to pressure, a supporting-bandage was ordered, and small doses of thymol (gr. 1-5) and ext. belladonna (gr. 1-20) were prescribed. On November 20, I saw the case again. The general abdominal swelling had materially increased, the special tumor was larger, but the nausea and the difficulty of urination were less. After a second examination, it seemed clear that the tumor was ovarian, but, in the belief that, under the circumstances, operative measures were not for the time demanded, it was determined to try the efficacy of medicinal treatment, as recommended by Courty, who cites two well-marked cases of recovery. Chloride of gold and sodium, iron in various forms, iodide of sodium, iodide of potassium, and arsenic were given internally; to these were added inunctions of iodide of lead, iodide of potash, belladonna, and graduated pressure by rubber bandages. These efforts were successively tried without success; in fact, I am disposed to believe that the methods pursued were rather injurious generally than otherwise.

The tumor enlarged rapidly, and the general health of the patient depreciated. On December 6, she had a violent chill, ushering in a peritonitis of grave severity, accompanied by great dyspnœa. The peritonitis finally yielded to a large blister, 8 x 8 inches, and the internal administration of calomel and opium. After the subsidence of the acute inflammatory symptoms, a persistent nausea, with occasional attacks of diarrhœa, protracted the convalescence. She was able to go about the house by the middle of January, 1888; but was rarely without dragging abdominal pains, was unable to sleep well, had frequent attacks of dyspnœa, and, in consequence of impaired digestion, as well as because of the inroads made on her vitality by the growing cyst, her emaciation became marked. On several occasions, a suppression of urine, due to pressure on the ureters or on the kidneys, was a serious complication. Dry cups to the lumbar region and along the groin, followed by hot mush poultices, were effectual in relieving the condition. She declined an operation.

On March 3, a second attack of peritonitis threatened to terminate the case; it was treated by anointing the now large abdomen with oleate of mercury and extract of belladonna, one drachm of the latter to one ounce of the former, and by full doses of opium by the stomach. The patient was able to leave her bed in ten days and agreed to an operation for removal at the earliest practicable time. The preparatory treatment consisted in the administration of syrup of the iodide of iron, the use of Murdock's liquid food, meat-juice, milk, and milk punch, in addition to such table-food as she could take. Her digestion was assisted by pepsin in acid solution. The whole body was well rubbed once daily at bedtime with a mixture of sweet oil and whiskey, and her belly was anointed once a day with belladonna ointment, which, at least, was a source of great comfort. The bowels, which had become torpid, were regulated by drachm doses of extract of cascara sagrada,

supplemented by an occasional enema. The sluggish kidneys were stimulated by dry cupping and by small doses of digitalis, which also exerted a favorable influence on the shortness of breath.

The determination of a limit of necessary endurance may have by some psychological influence stimulated the vitality and so seconded the nursing and feeding that the general condition materially improved without cessation in the progress of the cyst or favorable change as to emaciation. April 11 was the time fixed for the removal of the cyst; the abdomen was then larger than it should have been in a pregnancy at full term; fluctuation could be elicited, but was not so marked as the distended abdomen would have suggested; the face, neck, chest, and limbs were very thin; and the skin, notwithstanding its sedulous care, was somewhat harsh. The direct preparations were simple. On the 9th, her room was cleaned and lime-washed, and all furniture save the single bed removed. A solution of carbolic acid was kept simmering on the stove. On the morning of the 10th, a glass of hot lemonade with a teaspoonful of heavy magnesia was given, fasting, and in the afternoon she had a dose of castor oil, followed, after several free evacuations, by one grain of opium. On the morning of the 11th, she was well washed, had a bowl of boiled milk for her breakfast, and at eleven o'clock a tablespoonful of brandy and thirty drops of tincture of opium.

The antiseptic measures were a solution of bichloride of mercury, 1 to 2000, used to wash the abdomen; two pounds of a 95 per cent. solution of pure carbolic acid, from which dilutions were made—1 to 30 for instruments and sponges, and 1 to 40 for use within the abdominal cavity; a solution of thymol, 1 to 1000, used to spray the abdomen before closing; and some finely-powdered iodoform, with a good supply of salicylated cotton.

The kitchen table and a backless chair completed the arrangements. After the patient was under the influence of the ether, my friends, Dr. A. H. Hulshizer, Dr. W. H. Hech, and Dr. William C. McFetridge, entered the room. Dr. Hech assumed charge of the ether, Dr. Hulshizer assisted me throughout the operation, and Dr. McFetridge took charge of the antiseptic solutions, gave the hypodermic injections hereafter mentioned, and had the care of hot bottles, etc.

The abdomen was well washed with the bichloride solution. After making the usual incision of about three inches through the abdominal walls, opening the peritoneum, and pushing aside a fold of omentum, the wall of the cyst was seen. As was expected, a sound introduced between the cyst-wall and the peritoneum revealed extensive adhesions, and the incision was at once enlarged to about six inches. Such of the adhesions as would not yield to the finger—and they were many—were tied with carbolized catgut ligatures and cut close to the cyst. Even after all adhesions within reach had been severed, the tumor seemed barely movable. It was evident that the walls were thick and fleshy in parts, and that the contents of some of the divisions were at least semi-solid. A trocar and canula with angular attachment for gum hose was plunged into the most prominent and apparently the largest division low down. After approximating the wall of the cyst to the canula as closely as possible, about a bucketful of thick brown fluid was run off; when the liquid ceased to flow, the sac was pulled out of the cavity as far as possible, a ligature thrown around the opening and tied. The evacuation of and traction upon this cyst enabled me to reach deeper adhesions which were treated as before, and then a second cyst or cystic division was emptied by the canula. I was then able by persistent manipulation and the severing of other adhesions to eventrate the mass; the pedicle was pierced by a small flat needle carrying a double carbolized silk thread; each half was tied separately and the ends of the thread brought around the body of the pedicle and tied again. The pedicle was cut about three-quarters of an inch from the ligature; it was well washed, dried, and dropped into its bed.

There remained to see that no oozing occurred, to clean and to close the abdominal cavity. There was almost no oozing. The cavity was carefully sponged out, and an almost hot spray of the thymol solution was thrown in, the folds of omentum which had been wrapped in a hot napkin—occasionally changed—were replaced, and the wound was closed by eight silver sutures, each enclosing the peritoneum. Over the line of incision a moist piece of lint, spread with iodoform, was placed and held in place by three broad strips of adhesive plaster, then a pad of salicylated cotton, and over all a bandage of double flannel. The bladder was emptied and the patient put in bed.

During the operation, an hypodermic injection of sulphate of atropia in a drachm of whiskey was given once when the respira-

tion became alarmingly feeble, and another of a drachm of whiskey alone was given at the conclusion of the operation.

I may note a little misadventure that afterward proved troublesome. One of the hot bottles placed at the patient's side, to maintain heat, must have slipped for a moment under her buttocks, and been the initial irritation of a bed-sore.

The subsequent nausea was a little obstinate. It continued during the first twenty-four hours, and yielded either to the returning vitality of the stomach or to the external application of an ice-bag and the internal administration of one-quarter of a grain of cocaine, given every three hours for four doses. The nurse was instructed in the use of the catheter, and used it for the first eight days. The diet was restricted for three days to beef-juice with brandy, and oatmeal gruel, with Apollinaris water to drink. After the fourth day, there being no nausea and no fever (the temperature was never above 100.5°), a gradual return to a generous diet was permitted. The bowels were moved on the sixth day by enema, after a dose of castor oil.

About this time, complaint was made of the bed-sore. I found it on the right buttock, with an ugly-looking slough. The slough was cut out, the cavity washed with carbolic acid solution, and filled with finely-powdered charcoal, covered with adhesive plaster. It was well washed out daily with a syringe, and refilled until it healed by granulation. This was the only untoward symptom or circumstance following the work. The bowels assumed a regular action, and the bladder, glad to be free from the unwelcome catheter, behaved better than it had done for months. With a good appetite satisfied, the continuance of the sweet oil and whiskey bath daily, and the tonic influence of hope, assured, every day, added strength to the patient. Four weeks after the operation, she went to Salem, N. J., to recuperate further, and I am advised that she is quite well.

In looking over the case, it may be questioned why I did not tap for relief. The temptation to do so was great, but, independently of the danger of the procedure, which might have been considerable, it could only defer what should be the termination of the case. Tapping could not even promise with certainty considerable relief, for the fluctuation was not very marked; it might strengthen the patient's disinclination to have the cyst removed, and it was at variance with my opposition to half-way measures after a definite conclusion had been reached. I did not weigh the mass and contents, but I was assured by the patient's husband that the fluid and solid material weighed fifty-seven pounds. After removal, the smaller divisions were opened and found to contain a semi-solid brown substance, which could be pressed out. The cyst-walls were thick and fleshy in parts, and thin and softened in other parts. My friends agreed with me that the cyst would, at no distant day, have ruptured.

Of such a work, it may be said that the gravity of possible consequences, the traditions of the past, and the preceding grave symptoms have attached to it a formidable name and an importance somewhat at variance with the simplicity of its performance and the proportion of good results. The busy practitioner has daily on his lists cases infinitely more obscure as to character, more difficult as to treatment, and less hopeful as to results.

Dr. G. G. Davis, in opening the discussion, said: I wish to take exception to the preliminary remarks of the reader, that his case demonstrates that it is right for the general practitioner to undertake this class of operations. I hold that no one should open the abdomen unless he is prepared for whatever may be found, and we know that the most experienced operators tell us that they cannot be positive, in advance of incision, of the conditions that they will meet with. It may be, as here, a very simple matter, or it may be a very serious one. Only those who have had a certain amount of preliminary training, and are prepared to follow up the operation by the most radical procedures, if necessary, should do these operations. One case cannot be considered as establishing a principle.

Dr. Goodell: There is one point I wish to call attention to in connection with this graphically detailed picture of an ovariotomy, and that is the danger of having sloughs produced by hot water, to which the author has alluded. In a case of oöphorectomy for fibroma, of which I am cognizant, the flannel in some way became probably displaced from the hot bottles, and two severe burns of the heels were caused, the recovery from which was more tedious than from the operation. One other little point: It is a mistake to introduce the trocar at the lower angle of the wound; for, as the cyst empties, it collapses and may slip off from the trocar. The rule is to introduce it at the highest angle of the wound, so that it may have room to travel down with the collapsing cyst.

Dr. Chestnut: The case was not presented as a single one to establish a rule, but as an additional illustration to the many on record that, under antiseptic precautions and under proper circumstances, the general practitioner who has confidence enough to do surgery at all may also do an operation like the one reported.

Periscope.

Tuberculous Ulceration of the Vulva.

Dr. M. Zweigbaum, of Warshan, records a case of this rare manifestation of tuberculosis in the *Berliner klin. Wochenschrift*, May 28, 1888. The patient came under his observation in 1885, but the year before had been treated for fungous ulceration of the vaginal portion of the uterus. Paquelin's cautery was used, and the patient was discharged "cured." She was thirty-two years old, and had had five children. On admission under Dr. Zweigbaum's care there was a deep painful ulcer just within the left posterior vaginal wall, forming a cavity an inch and a half long and an inch deep, together with cauliflower excrescences of the portio vaginalis. The left labium minus was almost destroyed by ulceration, and microscopic examination of a portion revealed abundant tubercle bacilli. The apex of the right lung showed obscure signs of phthisis on auscultation and percussion. The spleen was somewhat enlarged, and the patient was feverish. In five months death ensued from exhaustion, the lungs having shown further alterations. There had been purulent expectoration, and toward the end œdema of the lower limbs. Syphilis was positively excluded in this case, which was examined by several colleagues. Dr. Zweigbaum has carefully examined the literature of the subject, and finds only two cases of tuberculous ulceration of the vulva recorded (Deschamps, Chiari). Taking into account the vagina and cervix uteri, twenty-nine cases of primary disease are recorded by various observers, and a short synopsis of each case is given. The disease is by no means rare in the course of general tuberculosis, but is rare when primary. Cohnheim gives one case, Fernet four cases, of infection by coitus. Others are ascribed to examinations, or syringing by nurses who are tuberculous or much in contact with tuberculous patients. Numerous cases are recorded as having occurred immediately *post partum*. Intercourse with phthisical patients appears also to be more or less dangerous; for example, by the use of the same bedclothes, closets, or baths. Autoinfection may also occur from the sputa or feces, and thus a secondary tuberculosis may be set up. Frerichs disputes the possibility of infection from without, and argues that it takes place by conduction from the Fallopian tubes, more rarely the uterus. The stages successively occupied by infectious material are very difficult to make out, because each organ or part successively traversed may show no trace of the virus afterward, the nidus being unsuitable. We do not yet know the conditions which favor the establishment of the tuberculous process in a particular part. It is probable that certain pathological processes induce a predisposition for tuberculosis, as in the lungs. These comments of Dr. Zweigbaum on his case teach us above all the value of cleanliness, or rather the great dangers which attend its absence.—*British Med. Journal*, June 23, 1888.

Case of Intracranial Abscess.

At the meeting of the Medico-Chirurgical Society of Glasgow, April 6, 1886, Mr. Henry E. Clark reported a case of this kind. A disc of bone removed from the skull by trephining in a case of intracranial abscess was shown. The bone was very thick, and was quite devoid of diploë. It was pierced by a small opening, only large enough to admit a silver probe, through which pus had discharged before the operation. The abscess was situated at the back part of the left parietal and temporo-sphenoidal lobes, and gave rise to no motor phenomena, and only doubtful sensory ones. The patient had experienced two attacks of inflammation of the middle ear, one five years before and the second within the previous six months. About four months previous to the operation, the discharge from the ear ceased, and he then had severe headache, followed by the formation of a swelling over the posterior parietal region. This was lanced and pus evacuated, leaving a sinus, which continued to discharge at the date of the operation. On removing the disc of bone, pus freely welled up through the ragged dura mater, and on introducing a probe the cavity was found to lead down to the petrous portion of the left temporal, which was found to be eroded, but the opening into the middle ear could not be made out.

Mr. Clark drew attention (1) to the existence of a large abscess, without signs of

pressure, on the cerebral cortex; (2) to the fact that the man was a prisoner awaiting his trial for assault, and the question arose as to the possibility of the cerebral affection having something to do with the excitement under which the assault took place; and (3) to the very small opening through which the pus escaped. Mr. Clark thought it probable that the opening was accounted for by the pus having followed the course of an emissary vein placed in an abnormal position.—*Glasgow Med. Journal*, June, 1888.

Cerebellar Hemorrhage.

At the meeting of the Royal Medical and Chirurgical Society, June 12, 1888, Mr. A. Ingle (Shelford) read the notes of a case which occurred in a widow 63 years old. Ten years before she had had an attack of paralysis on the left side, from which she recovered, the only remaining defect being a slight lisp. She had been subject to bilious attacks, and had often complained of giddiness in the head. On February 12, 1888, she walked a mile to chapel, sat the service out, and afterward it was noticed she was looking unwell. She walked into the vestry, thinking one of her bilious attacks was coming on, but, feeling much worse in the course of an hour, she was helped to a neighbor's house, and soon afterwards vomited. She was put to bed, and became very drowsy. Several attacks of vomiting occurred during the day. She would mutter replies to questions, but one could get but very little information from her. She complained of no pain except headache. There was some retraction of the head; pulse 88, regular, fair volume and strength; arteries somewhat atheromatous; the first sound of the heart was not quite clear, but there was no definite murmur; the pupils were equal and active to light; no arcus senilis, no loss of power or sensation. Next day her condition was unchanged, but there was no further vomiting. On the 17th there was some loss of power in the left arm, and the urine occasionally dribbled away; the patient lay in a drowsy condition, but seemed to hear whatever was said in the room, and would occasionally interpose a remark. By the 20th the left arm was entirely paralyzed, also some muscles on the left side of the face. Two or three days later the tongue was protruded to the right. She lingered till the 27th—fifteen days from the commencement—occasionally passing for several hours into a comatose state (once for forty hours), when she would be perfectly still, taking nothing, and not being able to be roused. For the last forty-eight hours she was in this condition. There was no evidence of loss of co-ordination. The following were the notes of the *post-mortem* examination: Very thin and soft skull. Much senile atrophy of convolutions and accumulation of subarachnoid fluid. No softening or lesion on exterior. Occupying position of right claustrum was a small cyst three-quarters of an inch deep by one-sixth inch broad, containing clear serous-looking fluid. In left cerebellar hemisphere was a large hemorrhage, chiefly in region of convolutions, involving only posterior part of whole cortex. This extended a little to the right of the middle line. There was, besides, a small hemorrhagic softening in the posterior wall of the posterior cornu of the right lateral ventricle, but no blood in the ventricles. Much atheroma of cerebral arteries.—*British Med. Journal*, June 16, 1888.

Insanity following Operations upon the Female Genitalia.

At the meeting of the Second Congress of the German Gynecological Society, at Halle, Werth, of Kiel, stated that of 270 women upon whom he had performed laparotomy he had observed in six insanity (melancholia) after the operation. Three of these patients were predisposed by heredity. The first symptoms showed themselves in one case five weeks, in a second eight, and in the remaining, several weeks after the operation. The duration of the disease was from two weeks to eight months. In one case recovery resulted, in two improvement, one patient committed suicide, in two the insanity remained stationary. The operations performed were: Castration, hysterectomy, and myomotomy. The cause of the insanity is not easy to determine. Iodoform cannot be charged with it, as it was not employed in all the cases, and was only used in moderate amount. In three cases a violent psychic or moral cause seems to have furnished the occasion of the attack.

Sänger, of Leipsic, said he believed that in such cases the patients were already diseased, and that the operations furnished only the occasion for the outbreak of violent symptoms. In three cases in which he obtained autopsies, he found in one an encephalitis, in another a hemorrhage into the pons Varolii, and in a third, exostoses upon the skull. It would perhaps be notice to thoughtful men not to operate.—*Wiener med. Presse*, June 17, 1888.

Uterine Appendages and the Sexual Appetite.

At the meeting of the British Gynecological Society, June 13, 1888, Mr. Lawson Tait read a paper on the influence of removal of the uterine appendages on the sexual appetite. He pointed out that in many respects the popular beliefs on the subject were remarkably erroneous, as, for example, that the removal of both testicles deprived a man of the power of fertilization and also of engaging in sexual intercourse. He could find no fact in support of this view; it was based apparently on a false analogy. Of course if the testicles were removed before puberty, it might be true, but it did not apply to the removal of the testicles of an adult. In animals, the desire and the power often survived, though the females seemed to "spot" the imperfection and refused approach. He only knew of one case of removal of both testicles in an adult, and in that instance sexual intercourse, after a time, had been resumed with as much satisfaction as ever, though after the first two years no emission took place. He hoped that the history of other cases of a similar kind would be forthcoming. He was convinced that the ovaries had as little to do with the sexual appetite in women as, say, the front teeth. He mentioned the cases of seven women whose ovaries had been removed while they were still virgins, and in whom, when married, no lack of sexual appetite was complained of. Still more remarkable was the evidence obtained from three young women in whom the uterus also had been removed while they were virgins. All of them gave evidence of strong sexual appetite. He concluded that, in men, the sexual appetite has not its seat in the testicles, and in women not in the ovaries, the tubes, or the uterus.

Dr. Bantock said that in several cases the women had found no difference after the operation in the matter of sexual propensity. He found that in horses it was by no means uncommon for a colt to have an erection even when castration had been performed before puberty. He had heard that eunuchs were quite capable of complete erection.

Dr. Harvey mentioned the case of a Jewess whose ovaries he had removed for severe menorrhagia, who made his life a burden by her complaints of having been deprived of sexual feeling. He said that as she did not know what had been done, her tale was probably a true one. He recalled that in India, where eunuchs are still made, it was generally held that unless a "clean sweep" was made of all the organs, including the penis, they were still capable of having intercourse.—*Medical Press and Circular*, June 23, 1888.

Intracranial Bullet-wound.

The Vienna correspondent of the *Medical Press and Circular*, June 23, 1888, says that at a recent meeting of the Imperial Royal Medical Society of Vienna, Prof. Von Mosetig showed a man, twenty-five years old, who had tried to commit suicide by shooting himself; the bullet had entered the skull through the temporal bone. On the day after the attempt at suicide the following symptoms were found to be present: Consciousness was intact; complete hemiplegia on the left side, which had supervened immediately after the shot; paralysis of the two lower branches of the facial nerve, the upper branch of this nerve being quite intact; paralysis of the hypoglossal nerve; a distinctly pronounced dorsal clonus in the right leg; epileptiform attacks of the paralyzed extremities, established on the third day after the injury. A wound the size of a pea was discovered over the right temporal bone, at about five centimetres above the zygomatic arch. Professor Mosetig wished to emphasize the fact that hemiplegia had occurred immediately after the lesion, as such motor disturbances are usually observed at a later period, when they are due to subdural hemorrhage. As no symptoms pointing to an increase of the intracranial pressure were present, Professor Von Mosetig determined on desisting from any surgical intervention, and applied a moist bandage of iodoform gauze. A bloody and serous exudation continually discharged from the wound for about five weeks. If the wound, in this case, had been permitted to heal under the formation of a dry scurf, retention of secretion and other disturbances would, no doubt, have been the result. The bladder and the intestines acted well. No disturbances of sensation or nutrition. The symptoms referred to began to improve during the course of the third week; at first, the paresis of the facial nerve, and later on the paralysis of the hypoglossal nerve disappeared; the patient began to speak. In the course of the sixth week, electrical treatment was resorted to, and the rest of the symptoms also disappeared. Ultimately only a hemiparesis and symptoms of contraction were present; moreover, a reflex athetosis or "chorea posthemiplegica" was to be observed, which supervened only when the patient began to yawn. The

tendon-reflexes were augmented and the dorsal clonus was present to a lesser degree. The patient recovered his normal speech, and the wound over the temporal bone healed up. The question arose as to the seat of the bullet. There is no doubt, he says, that he had to deal in this case with a lesion of the cerebral cortex, probably with an affection of the central lobe, so that the centres of the hypoglossal, the facial nerve, and the lobus paracentralis for the lower extremity became necessarily affected. The contraction and the "chorea post-hemiplegica" also plead in favor of a lesion of the cortex. The patient was able to stand upright for a while, but he could not do so when his eyes were closed. Professor Mosetig shares the opinion of Professor Nothnagel, and holds that any surgical intervention would be contra-indicated in this case. They might, indeed, succeed in removing the bullet, but he thinks there is scarcely any doubt that changes have already taken place on the surface of the brain which render a complete recovery highly improbable.

Tuberculosis of the Iris.

The Vienna correspondent of the *Medical Press and Circular*, June 23, 1888, states that at a recent meeting of the Imperial Royal Medical Society of Vienna, Prof. Fuchs brought before the society a case of tuberculosis of the iris. The patient, a girl, six and a half years old, had suffered from measles and hiccough, and later on she was the subject of small-pox and scarlet fever, with œdema. About four weeks after the last disease an inflammation of the eye supervened, which Prof. Fuchs recognized as being tuberculosis of the iris. Some relatives of the patient had died of tuberculosis; the patient was well-developed, and the apices of her lungs were sound. The cornea was found to be dim in the right eye, and small deposits were visible on its posterior surface. The internal part of the pupil was covered by a tumor which reached as far as the cornea, and consisted of many small nodules of a yellow-red color. Numerous blood-vessels were present on the surface of the swelling; similar nodules were also to be noticed over the rest of the iris, and even on the lenticular capsule. Prof. Fuchs remarked that he had not hitherto met with such a form of tuberculosis. This disease was usually observed under two other forms, viz., in the disseminated form where many small and gray nodules were scattered over the iris; and the second form was the conglobulated one, in which several conglomerated tubercles penetrated through the cornea and underwent a caseous process on its surface. While the disseminated form of tuberculosis, in most of the cases, is observed in both eyes, causing occlusion of the pupil, the conglomerated tubercle bears a great resemblance to a neoplasm. Virchow describes it as a granuloma of the iris, and its true character has been recognized only in modern times. As to the case under consideration, he said it was a transitory form, with a tumor which was composed of many small swellings. The patient was, moreover, affected with a tumefaction of the submaxillary lymphatic glands of the right side. The case was to be considered, he said, as one of primary tuberculosis of the iris. Prof. Fuchs was of opinion that the affected eye ought to be removed in order to avoid general tuberculous infection.

Microbes in Skin and Suppuration.

Dr. V. A. Kryloff, who has been investigating the causes of acute suppurative processes, has obtained some interesting results by rubbing antimonial ointment and croton oil liniment into shaved patches of the skins of different animals. When these substances were rubbed into the skin of guinea-pigs and rabbits, no pustules, as a rule, were produced; but by means of very energetic rubbing a dry gangrene of the skin was caused, in which no micro-organisms were to be found—a condition apparently due to an absence of pyogenic organisms in the skin of these animals. In one case, however, there was pustulation, and staphylococcus aureus was found. When a similar experiment was tried on dogs, pustulation always followed, and staphylococcus pyogenes albus was invariably found; this coccus existing, as it would seem, in the skin of the dog, otherwise it would be difficult to explain why other staphylococci were not found. Cultures were also prepared from the normal skin of dogs which, injected into other animals, produced abscesses, and in the case of rabbits proved rapidly fatal. The conclusion that Dr. Kryloff comes to is that the production of pustulation by external irritants depends, in part at least, on the presence of pyogenic organisms in the skin. In the case of dogs, he thinks that they must be localized in the deeper layers of the epidermis, as thorough disinfection was a very difficult proceeding; and unless the organisms lying deeply were destroyed, their power of provoking suppuration was not arrested.—*Lancet*, June 9, 1888.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.25**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CHLOROFORM AS AN ANÆSTHETIC.

Dr. Chisolm's recent paper, "*A Very Valuable Lesson for Those who use Anæsthetics*," brings up not only the question of the proper treatment of suspended animation from anæsthetics, but also that of the choice of an anæsthetic agent. Dr. Chisolm estimates that chloroform has been administered under his charge at least ten thousand times, without a death. Four cases of suspended animation have occurred in this series, which were successfully treated by the method of Nélaton—suspension of the patient by the heels. The detailed account of these four cases adds convincing testimony to the value of this plan of treatment. Dr. Marion Sims, in *The Story of My Life*, gives a graphic account of a similar successful case in which the treatment was supervised by Nélaton himself: three times were the functions of the heart and lungs restored by suspension, and as often they failed when the supine position was resumed. "It is the horizontal position which is fatal in chloroform-poisoning," Dr. Chisolm says, and adds: "I feel convinced, from my own experience with this invaluable method, that many of the dead from chloroform might have been resuscitated had the surgeon hung up immediately by the feet the inanimate body, instead of wasting time in applying hypodermic injections, cold water splashing, spanking, fanning, electricity, or even attempts at artificial respiration. . . . Do any or all of these things if you will, but hang up the patient first, and that instantly, as soon as the heart and lungs fail." The method is equally applicable to the lesser grades of heart-failure, and to the same conditions when brought about by ether.

The method of treating obstructed pharyngeal breathing employed by the author is deserving of especial emphasis because of its practical importance. "Should snoring occur," he says, "indicating some difficulty in pharyngeal breathing, the chin is drawn forcibly upward. This elevation pulls the anterior wall of the pharynx, with the byoid bone and root of the tongue, forward, making for the air a clear and straight passage from the nose into the lungs. By this movement of the chin, respiration becomes immediately quiet and easy. The pulling-up of the chin is a much more efficient means of pulling the root of the tongue forward than by pulling out the tongue with the forceps, as is recommended by some surgeons. It is not always easy at this stage of anæsthesia to get into the mouth, as the lower jaw-muscles may not be relaxed. A proper tongue-forceps is not often at hand, and to tear the tongue-substance with sharp-toothed and yet slipping instruments, with the soreness and swelling which subsequently follow, is an abominable practice which should be abolished. The patient's chin and your own hands are always present, and it only

needs knowledge of the method to apply it, and to secure prompt and speedy relief."

The belief has been growing stronger of late that ether is not so safe an anæsthetic as has been supposed. Emmet, about 1865, had a death from ether anæsthesia. The woman was suffering from cystitis and pyelo-nephritis. After this death, he established the rule in the Woman's Hospital that the urine of all patients should be examined prior to etherization. He states that he has had five other cases of fatal suppression of urine where this rule was neglected by his assistants. It is a clinical fact which has been long recognized that persons with certain diseases of the urinary organs do not stand operations well. Especially is this true of persons with surgical kidney. They die shortly after operation from anuria with uræmia. It has been supposed that death is due to shock from the operation; but it is now known that the principal cause is irritation of the kidneys with ether. Reports of serious illness and death from ether-uræmia have not been rare in the last few years. So real is this danger, that some of the most conservative surgeons in America have abandoned ether as an anæsthetic. There is unquestionably a strong reaction against the dictum that ether alone shall be used for the production of anæsthesia in surgical practice, and a desire that the relative indications for the use of chloroform be better defined. While professional opinion is not yet sufficiently crystallized for dogmatic assertion, yet it is quite well established that ether is badly borne at both extremes of life (since it is apt to set up a bronchitis, or to intensify one already present) and by chronic drunkards; and that it is very fatal in cases of fatty heart and of nephritis. Chloroform, on the other hand, is well borne by the young and the old, by pregnant and parturient women; and it is not known to have any irritating effect upon the kidneys. It is almost universally recommended in tracheotomy. Deaths from chloroform generally have been among adults. Deaths have occurred during the administration of chloroform, where there was reason to believe that fear of the anæsthetic was the cause of the fatal result.

In the present state of our knowledge, the use of chloroform for the production of anæsthesia is justifiable during labor, in persons suffering from acute or chronic disease of the kidneys, in tracheotomy cases, and in the young and old, especially when they are suffering from bronchitis. Ether should not be given to persons suffering from diseased kidneys.

A DANGER TO THE CHILDREN.

We have already, in the REPORTER, called attention to certain sources of danger to the health of the young—not strictly medical—which we think it right for physicians to notice, and so it will not excite much surprise if we step a little aside from the usual and beaten track of medical journalism to point out another source of danger which sometimes comes in a most alluring and seductive form. We refer to the stories and illustrations contained in many of the periodicals published ostensibly for the good of little mankind. We do not in this refer to those despicable sheets published plainly with no other object than to get money by appealing to the coarse and rude part of children's nature. These are too gross to require our condemnation. We refer now rather to those which bear the imprint of well-known and highly respected publishing-houses, and which have a laudable purpose mixed with the entirely proper design of making money.

Some of the very best of these seem to overlook one possible effect on children of the thrilling stories they contain, or of the blood-curdling pictures which illustrate them. It has not been six months since we called attention to an instance in which the paper called *Wide Awake* erred in this respect (since which, by the way, we have ceased to receive it), and now we call attention to what we believe to be a defect in that otherwise excellent periodical, *Harpers'*

Young Folks. This paper is in many respects so admirable that we regret to find it publishing stories in which the moral is brought in at the expense of a suggestion of immorality, and in which escape from danger is made the more striking by too graphic a description of the danger itself.

The effect of this sort of thing is so injurious to the bodily and mental health of young children, that we think it quite within the province of a medical journal to call attention to the fact. It is a great pity that a paper published for children should be of such a character that a parent cannot place a copy of it in the hands of his little ones without cutting out some of the pictures, or charging the nurse that she must not read certain of the stories—or parts of them—to the children. Yet this is precisely the case with *Harpers' Young Folks*, and we should regard any parent as careless of the mental development of his children who would let it come into their hands without carefully examining each copy to see if it were fit for them, in respect to the matter we are discussing.

No one can tell what horrors of night, and what torments of daily terror, are caused by the things with which some persons entertain children. Recollection of one's own experience, and observation of the experience of the present rising generation might convince the least observant that this is no fancy or prejudice which we urge upon their notice, and we would be glad to know that what we now say had the effect of riveting the attention of those who make books and papers for the young, upon the opportunity for harm which they present together with their opportunities for good. We have no doubt that the publishers of *Wide Awake* and of *Harpers' Young Folks* give much thought to the latter, but we fear they have sometimes overlooked the former. For this reason, and with a full appreciation of the good they have accomplished in certain directions, we call their attention, as well as that of our readers, to a matter which, in our judgment, calls for amendment.

A DETAIL OF COLOTOMY.

An interesting discussion has arisen lately in Germany in regard to the value of a step in the operation of colotomy, which was described by KNIE, of Moscow, in the *Centralblatt für Chirurgie*, May 5, 1888. The method suggested by Knie has been practiced by him only on dogs. It consists in opening the abdomen transversely in the region of the transverse colon, sewing the peritoneum to the edges of the wound in the belly-wall, drawing out the colon, making an opening through the mesocolon with a blunt instrument, and closing the abdominal wound with two or three stitches, which are passed through the opening in the mesocolon. The effect of this is to have a portion of the colon wholly outside of the abdomen. This loop is to be carefully stitched at each side to the edge of the (now) two abdominal openings, after which it is to be immediately incised, excised, or let alone for awhile, as the circumstances of each case may demand.

This ingenious method has attracted so much attention as to call forth articles by Maydl, of Vienna, and by Lauenstein, of Hamburg, in which they show that they had, previously to Knie's communication, performed operations essentially the same in principle. Maydl describes a number of operations in which he practiced his method, which consists in opening the abdomen at any suitable point, drawing out a loop of intestine, making an opening through the mesocolon, or mesentery, passing a piece of iodoform gauze through this, and stitching the loop of intestine to the parietal peritoneum, and its two parts together below the gauze. Lauenstein describes two operations on human beings, in which he had already done exactly what Knie afterward suggested, with the exception that he closed the abdominal wound by sutures, which simply passed through the mesocolon, so that no formal opening was made in it. In speaking of his operations, Lauenstein properly calls attention to the fact that they were founded upon

the experiments of Panum, reported in 1885, on the behavior of loops of intestine which had been fastened outside of the abdominal cavity.

The method of Lauenstein seems to be, of those suggested, the one best suited for operations upon any movable part of the intestinal canal, while that of Maydl may be more suited to operations close to the rectum. The important feature of all the methods we have described is that they enable a surgeon to secure a portion of intestine wholly outside of, and shut off from, the general cavity of the peritoneum, upon which he may carry out further operative procedures at once, or after the lapse of a considerable interval. This is a matter of so much importance that it might make the difference between operating or not operating at all in many cases. The possibility of having an extra-peritoneal portion of the bowel still nourished by the vessels of its mesentery, and capable, as Panum has shown, of maintaining its vitality and adapting itself to its unnatural situation, must encourage surgeons to operate in cases which, but for this, would be beyond assistance.

The question of priority involved in the discussion alluded to is not important and seems easy to settle; but it is, perhaps, proper to say that, in general, Lauenstein's method is not only the simplest, and easiest to execute, but also the most scientific and most promising. It is a fortunate thing when all these elements are to be found in a single method.

LOCAL SUN-BATHS FOR HYDROCEPHALUS.

Among the methods recommended for the treatment of chronic hydrocephalus in infants is one cited in the *Wiener med. Presse*, June 10, 1884. It was proposed by Somma, and has been employed by him in five cases with good results. The method consists in exposing the bare head of the child to the direct rays of the sun for half an hour at a time for four or five days, and afterward for periods gradually increasing to forty or fifty minutes until a month has elapsed. When the treatment is applied, the child's face must be turned away from the sun.

If it were not for the fact that chronic hydrocephalus is a disease so rebellious to treatment that almost any suggestion is acceptable, we would hesitate to place this one of Somma before the readers of the REPORTER. But in no case does the adage "any port in a storm" apply more forcibly than in the treatment of chronic hydrocephalus; and so we overlook the somewhat confused explanation of the *rationale* of his method given by Somma, and bring this method alone to the attention of our readers in the hope that it may be more useful than its explanation is clear.

TREATMENT OF HEAT FEVER.

The principles upon which a case of heat fever should be treated have been practically settled since the publication of Dr. H. C. Wood's researches on the subject. It is of decided advantage, however, for the practitioner, besides knowing these principles of treatment, to have an efficient and simple method of applying them. Such a method has been described by DR. F. A. PACKARD, in his report of thirty-one cases of heat fever seen by him while resident physician at the Pennsylvania Hospital, during the summer of 1887 (*American Journal of the Medical Sciences*, June, 1888). In every summer a large number of cases of heat fever are brought to the Pennsylvania Hospital, and the treatment adopted there is the result of years of experience. During the time of Dr. Packard's experience, as soon as a patient with heat stroke was brought to the hospital, he was placed on a waterproof fracture-bed (which was kept under a tent in the open air), his clothing was removed as quickly as possible, a thermometer was introduced into the rectum, and ice was packed about the body and extremities. As a rule, fifteen or twenty minims of

tincture of digitalis were administered hypodermically. The thermometer was removed and examined every seven minutes, the icing being continued until the temperature fell to 104° F. The patient was then dried and put on a clean bed, with an ice-cap applied to his head. The icing was not continued after the temperature in the rectum had fallen below 104° F., because experience showed that if continued after that time the fall in temperature was too rapid and great, and a condition was brought about which required the application of external heat and free stimulation.

In cases in which the initial temperature was only 106° F. or under, it was found sufficient to strip the patient and sponge him liberally with a mixture of one part of alcohol and four parts of iced water, applying at the same time an ice-cap to his head. In addition to this routine treatment, other means were employed to meet individual symptoms in various cases. Thus, when convulsions occurred after the temperature had been lowered to a considerable extent, morphia was administered, and usually with good effect. Again, when the respiration and pulse failed to improve in character with the fall in temperature, the patient was bled in spite of the feeble pulse. This almost invariably produced quieter, fuller respirations, with a soft steady pulse. It was generally necessary to bleed from the arm, the blood being so thick that it had to be squeezed out by stroking the arm up from the hand. The loss of twelve or sixteen fluidounces of blood sufficed to bring about marked improvement.

From the experience in the Pennsylvania Hospital, the essential points in the treatment of heat stroke may be summarized as follows: Put the patient in the shade, where there can be as free a circulation of air as possible; strip him, and, if the temperature is above 106.2°, apply ice to the body until the temperature falls to 104°; then dry the patient and put him to bed with an ice-cap to his head. If convulsions occur at this time, use morphia; if the circulation and respiration do not improve with the fall in temperature, bleeding may be employed.

In addition to these practical and easily-remembered rules for the treatment of heat fever, we would remind our readers of a suggestion made by Dr. Morris J. Lewis in the MEDICAL AND SURGICAL REPORTER, August 6, 1887, that the physician would do well to carry with him a watery solution of antipyrine, two drachms to half an ounce, and administer at once twenty minims (ten grains) hypodermically, in order to bring about an early fall in temperature before other means can well be effective.

ANOTHER MEDICAL AND SURGICAL REPORTER.

We call the attention of our contemporaries, and of our readers, to the fact that a journal has been started at Toledo, Ohio, which has adopted the name of the *Medical and Surgical Reporter*. This is a mistake which we trust will be at once corrected; because our amiability can hardly be stretched so far as to approve of the appropriation by another journal of a title which owes whatever worth it has to the long career and success of the MEDICAL AND SURGICAL REPORTER of Philadelphia.

CORRESPONDENCE.

Official and Officinal.

TO THE EDITOR.

Sir: Would you please answer the following in THE MEDICAL AND SURGICAL REPORTER?

Prof. Bartholow says any drug recognized by the U. S. Pharmacopœia is *official*, and drugs kept in the shops *officinal*. He uses official exclusively in his work on Materia Medica. I cannot find any authority that sustains him. By answering the same fully you will greatly oblige

Yours truly, READER.

Reading, Pa., July 3, 1888.

[Dr. Bartholow is right—"Official" is what is sanctioned by the Pharmacopœia; "Officinal" is what is sold in the shop, or "*Officina.*" Editor of REPORTER.]

Snake-Bite.

To the Editor.

Sir: Reading an editorial in the Medical and Surgical Reporter of June 9, 1888, upon "Snake-Bites," induces me to send you this. Having had a large experience in treating snake-bites, I am led to the conclusion that whiskey possesses no antidotal properties over the virus of the snake. It is simply given because it is popular. The poison of the snake, bee, wasp, spider, &c., is an acid. Whiskey has no alkaline properties, hence it is no antidote. That I may be understood, and for illustration, say that it takes gr. ⅛ of strychnia to destroy life, and if a man swallows this quantity, unless some antidote is used to destroy the effects of the poison, he will die. If the poison is neutralized before it does its deadly work, the man will recover. It is very evident that if it took one-eighth of a grain to kill a man, one-tenth of a grain would not kill. The man who has taken one-tenth of a grain will get well without any treatment. Now if it takes of the poison of the snake two grains by weight to kill, it is sure that one grain will not kill. If two grains enter a vein and are carried directly to the heart, they will produce paralysis of the heart, and the patient will die before an antidote can be given. If one grain enters the vein, and is carried to the heart, it will not kill, because it takes two grains to kill. We demonstrate this theory in our practice every day. We give our patients gr. 1-60 of strychnia; they do well.

Now we see why it is that whiskey is the universal remedy for snake-bite, and why so many believe it is infallible, when the truth is, the patient would have gotten well and been saved the intoxication.

I do not give whiskey in snake-bites. My theory is, that I have an acid poison to deal with, hence I give alkalies—spirits of ammonia, with a prompt emetic. The permanganate of potash is good, just in proportion as it neutralizes the acidity of the poison, and it is always well to support the heart's action with digitalis.

Yours truly, J. C. Milner, M.D.
Comanche, Texas,
June 19, 1888.

—Sir Morell Mackenzie declares that for the present he is debarred from answering the charges made against him by the German doctors, though he is preparing his own report of the disease of the late Emperor Frederick, and hopes to obtain permission to publish it later on.

Notes and Comments.

Drug-Stores in Germany.

A correspondent, writing from Dresden, says: "The drug-stores have a curious way here of shutting up just about the time you want them. And as soon as it begins to grow dark, down go the shutters; and if you need anything, you go to a little bell-handle outside of one of the iron shutters, and ring it. Then you hear some one at a crank inside; the massive frame rolls up, and a head looks out of the window. Finally the man or boy inside opens part of the window, and you talk through a pane of glass and make known your wants Instead of getting angry at being aroused, the man begs your pardon for keeping you outside and says: "I thank you for your order." If you have not the exact change, and the man inside is in the same predicament, he will beg you most politely, and thank you, to allow him to change it. Having done so, he will thank you for calling (evidently taking the visit as a social one), bow, close his little peep-hole, bow again, and then smile sweetly as he grinds down his iron shutter, and his smiling face is lost to view. How different from the druggists in America! I remember I once woke one up in the States, and he came downstairs with a shot-gun after me. But, as I remarked before, they have a curious way of doing things in Dresden."—*Phila. Ledger*, June 12, 1888.

Professional Secrecy Enforced.

The *Chemist and Druggist*, June 23, 1888, states that the Besançon court of appeals has just decided an interesting case in accordance with well-settled jurisprudence. Dr. Z., the director of a private hospital, published some time ago an advertising pamphlet relating at length the case of a Mme. X., a patient of his, who was, he alleged, suffering with monomania, but since then escaped from the hospital. About eight hundred copies of the pamphlet were circulated, in which the patient's identity was alluded to pointedly enough to be easily recognized; whereupon the State attorney, although no one had complained, prosecuted the doctor for a violation of the section of the Penal Code enjoining professional secrecy upon physicians, pharmacists, and midwives. The first sentence was two hundred francs fine and two thousand francs damages. Not satisfied, Dr. Z. appealed, and for his pains the Besançon court has maintained the damages, raised the fine to five hundred francs, and seasoned the whole with a scathing rebuke.

Religio Medici.

The Union League Club resolutions on the death of Dr. Agnew, prepared by Chauncey M. Depew and presented by Sigourney W. Fay, contain the following: "If all Christians were like Dr. Agnew, all men would become Christians. With him, religion was not a cloak, but a career; it was not a formula, but a faith; it was not alone a liturgy or a creed, but the practice during every working-hour of the commandment 'Thou shalt love thy neighbor as thyself.' The profession was not only enriched by his genius and science, but thousands of young men owe to him the opportunities and examples which will enable them to take up his work and follow in his steps. The loss of such a man in the prime of life and usefulness is a public calamity, only mitigated by his good works while living and his glorious memory after death." —*Boston Med. and Surg. Journal*, June 7, 1888.

A Possible Source of Infection.

To obstetricians, who need to be constantly on the lookout for possible sources of puerperal septicæmic infection, the report of the following case is interesting, as revealing a somewhat unusual, or at least unexpected, source of danger. It is sent to the *British Medical Journal*, June 9, 1888, by a correspondent:

"A few months ago," he states, "I confined a woman of her seventh child. Immediately after birth she developed unmistakable signs of so-called puerperal fever, which rapidly terminated in death. During and after the confinement, I carried out the strictest antiseptic treatment. Part of the *post-partum* treatment consisted in washing out the uterus with an antiseptic twice daily; for this purpose I used an ordinary Higginson's syringe, with large catheter attached. The catheter I provided myself, taking care to use one which had never been used for any purpose before. The syringe my patient provided me with was a new one. At the termination of the case I advised my patient's friends to burn the syringe and the catheter, this being, I thought, the surest way to prevent the possibility of subsequent infection from their being given out on loan. Quite recently I learned upon inquiry that the catheter had been burned, but the syringe had been 'returned to the chemist' from whom it had been borrowed at a moderate charge per diem. The poorer classes are, it appears, in the habit of borrowing syringes in this way, and one at least of my professional neighbors sends his patients to the chemist to hire one when he finds they cannot afford to purchase. It is not difficult to see how, under these circumstances, puerperal septicæmia may be spread. I bought from the chemist one of the two syringes he keeps on hire; the other he told me had not been returned. 'Indeed,' he added, 'I lose on an average one in the month.' Although I put the one I secured beyond the possibility of future harm, unfortunately it is impossible to identify it as the one I used some months ago, which means that the stolen one is at large, possibly carrying with it puerperal septicæmic influences."

We have never in this country heard of druggists who kept syringes or any other instruments for hire; but what has occurred in England may occur here. A word to the wise is sufficient.

New Operation for Incontinence of Urine in Women.

At the meeting of the British Gynecological Society, April 25, 1888, Dr. William Alexander read a paper on this subject, in which he said that the first case he operated upon was a woman belonging to the theatrical profession, who often had to retain her urine for unduly prolonged periods of time. This ultimately determined a paralysis of the sphincter of the urethra. To remedy the distressing effects of this condition of things, various methods of treatment were employed, but in vain, and ultimately he dissected out the urethra and led it into the rectum, hoping to utilize the rectal sphincter for the retention of urine. At the third attempt he succeeded, and the patient was much relieved. He also read the notes of two other cases on which he had operated for vesico-vaginal fistulæ by closing the vulva and carrying the urine into the rectum.—*Medical Press and Circular*, May 2, 1888.

Aromatic Vinegar for Disinfecting Sick-rooms.

The *Chemist and Druggist*, June 23, 1888, gives the following formula:

Camphor	℥j
Oil of cassia	f℥j
" pimento	f℥j
" bergamot	f℥j
" cloves	f℥j
" lavender	f℥ij
Acetic acid	f℥iij
Rectified spirit	f℥iij
Glacial acetic acid to	f℥xvj

Mix.

Mr. Depew on the Doctor.

We learn from the *Medical Record*, June 23, 1888, that Mr. Chauncey M. Depew, in his address before the Syracuse Medical College, spoke as follows concerning success in the doctor's life:

"I have no faith in mottoes, or maxims, or rules for success, and, though often asked, never have any to give. A young man who has good health, and governs his conduct by a conscientious answer to the ever-present question Would my mother approve? and gives tireless attention to his business, is certain to succeed. It is impossible for every one to win fame or fortune, or both; but the man who earns a living, even in a very modest way, feels the inspiration of independence, and has safely passed the precipice of failure. Repinings for riches and angry envy of prosperity weaken the moral tone and mental fibre. They paralyze effort, and end in empty vaporings in the bar-room and empty larders at home. The opportunities for accumulating large fortunes rarely come to members of the liberal professions. Their compensations are in the position and influence accorded to their culture and training. With them self-support is success, and when the surplus surely comes, and with it home, larger comforts, and fair competence for declining years, they enjoy a measure of happiness and content rarely found with the use and care of great wealth."

Successful Operation for Stenosis of the Pylorus.

The *Medical Record*, June 23, 1888, states that Loreta's operation, or digital divulsion of the pylorus for stenosis, with dilatation of the stomach, was performed June 11 by Dr. William T. Bull at St. Luke's Hospital, New York. The patient, a man thirty-seven years old, had suffered for twenty months from daily vomiting, pain, acid eructations, and heartburn, and was much reduced in flesh, despite treatment by lavage of the stomach, careful diet, and internal remedies. The fluids of the stomach were thoroughly investigated chemically by Dr. F. P. Kinnicutt, and the diagnosis of stenosis from cicatricial contraction of an ulcer arrived at. The operation confirmed the diagnosis, the pyloric orifice being found so small as to admit only a bougie of a diameter of three-sixteenths of an inch. Through a wound two inches long near the pylorus, the orifice was stretched gradually with bougies and the fingers till it was over two inches in diameter. No accident followed the operation, and the patient may now (June 19) be considered out of danger. There has been neither pain nor vomiting, though for several days considerable quantities of liquid diet have been taken by the mouth. A full report of the case will be presented at the October meeting of the Practitioners' Society. This is the first successful case of this operation yet reported in this country.

The Effect of Ergot on the Involution of the Uterus.

This has been carefully studied by Drs. Herman and Fowler, of England, and in a paper before the London Obstetrical Society they report two sets of patients—one set (58 cases) treated with ergot for a fortnight after labor; the other set (68 cases) given a single dose of ergot after labor, and no more. In the first set of patients the uterus diminished more rapidly in size than in those in which only one dose was given. As to the effect on the duration of the lochial discharge they did not find that the ergot treatment produced any appreciable effect.

Dr. Boxall, before the same society, contrasted two series of cases, each referring to one hundred patients. In the first series, ergot was given three times daily during the first three days after labor; in the second, ergot was omitted. His observation is that the practice of giving ergot during the days subsequent to delivery tends to prevent the formation of clots and to hasten their expulsion, and to diminish the frequency, intensity, and duration of after-pains.—*Practice*, March 15, 1888.

Naphthaline in Purulent Ophthalmia.

At the meeting of the Biological Society of Paris, May 19, 1888 (*Bulletin Médical*, May 23, 1888), M. Budin stated that he had employed naphthaline in two cases of purulent ophthalmia, in conjunction, however, with nitrate of silver, as he did not feel justified in using it alone. He first made one application of a solution of nitrate of silver to the eyes, and followed it with applications of a saturated aqueous solution of naphthaline. This he did for three days, and then discontinued the former. He recognizes the fact that the number of observations has been too small to draw trustworthy conclusions from, and yet the usual duration of the suppuration was so much shortened that he thinks the usefulness of the remedy should engage attention, and its proper mode of employment be learned by trial.

How to Administer Sulphonal.

The *Chemist and Druggist*, June 16, 1888, in an article on sulphonal, states that the sparing solubility of sulphonal is one of the chief difficulties which have to be dealt with in dispensing the remedy. It is placed on the market in the form of small white crystals, which powder easily, but the resulting powder mixes badly with water. Were there not this objection, the best form of dispensing sulphonal would be as powder, for, the dose being comparatively large (15 to 60 grains), pills are out of the question. The patient might, however, take a powder dry on the tongue and wash it down with water, or, better, it may be taken in rice-paper. In mixture, the drug requires the addition of something viscous to suspend it, otherwise the powder rises to the surface of the liquid as soon as agitation ceases. For a draught it advises the following formula as suitable one:

Sulphonal	gr. xxx
Syrup	
Mucilage of acacia	āā f℥ ii
Distilled water	f℥ i

Powder the sulphonal, and mix the syrup with it in the mortar, then the mucilage diluted with three fluid drachms of water. Wash out the mortar with the rest of the water. Dr. Lovegrove recommends compound tragacanth powder for suspending sulphonal, and this may be used if the viscosity is not objected to. The remedy makes a good pill with glycerine and tragacanth, but, as already stated, the dose renders this form of administration objectionable.

Sulphonal is practically tasteless, the extremely slight bitter after-taste of the aqueous solution being observable only to those who expect it, and not to the ordinary patient.

The Disinfection of Bedding and Clothing.

The *N. Y. Medical Journal*, June 16, 1888, says that in Paris the importance of destroying micro-organisms in every shape and wherever found seems ever increasing, as shown by the effort lately made in this direction by the directors of the great government loan offices called the *Mont de piété*. A large number of the poor classes pawn their bedding, and all sorts of mattresses, pillows, and other articles are received at the loan offices and placed in the storehouses, and, when we know that one of the number may be contaminated with the germs of some disease, and transmit it to the whole lot and cause an epidemic, as has been proved, the importance of disinfection of these goods will be recognized. It is only too common in all countries to see poor people, after a long illness, compelled to pawn their goods; and our local law-makers, together with those interested in hygiene, may see their way to purifying these goods or insisting that the pawn-shop people do it, by the means used in Paris. This is by superheated steam. A large cylinder to put the goods into is mounted on wheels, looking for all the world like a steam boiler or a fire-engine. This can be drawn by a horse wherever it is wanted, as was done lately during an epidemic of sweating sickness in the country, and the goods are placed in it for disinfection. During the few months that this plan has been working, thousands of old mattresses, pillows, covers, and clothes of all sorts have been steamed, and it is beyond question that millions of the invisible and dangerous microbes have been destroyed, and that another great step has been taken toward the millennium of cleanliness, and therefore of health, in modern cities.

This plan for public disinfection has already been referred to with commendation in an editorial in the REPORTER, June 30, but the subject is of sufficient importance to deserve urging even by repetition.

Marine Station for the University of Pennsylvania.

The Biological Department of the University of Pennsylvania is about to establish a station for original research and for instruction in forms of marine life. It is stated that a gentleman interested in this study is to give a large sum of money to the University for the endowment of the station, which will probably be in operation next summer.

It is said that the present plan does not look to the fixing of a permanent site for the station until, from a number of years' varied experience, the best spot has been found. It is proposed to get a large schooner, to fit it up with a steam pump, the ordinary laboratory equipments, etc., and to move in it from place to place. The students can either use the vessel as a means of conveyance, or meet it at the point which has been selected as the temporary station.

Professor Dolley, of the Biological School, is to go abroad to study next summer, and will visit, among other places, the great marine station at Naples, where he was a student some years ago.

NEWS.

—The New York Polyclinic is to have a spacious hospital in immediate connection with the college.

—Small-pox is epidemic in the town of Preston, about thirty-five miles north of Liverpool, England.

—There is said to be a genuine case of leprosy in Le Grande, Iowa, the victim being a young Norwegian.

—The tenth regular meeting of the State Board of Health of Pennsylvania was held in the Supreme Court Room at Harrisburg, July 11.

—The number of cases of small-pox at Havana, Cuba, is diminishing. Of a total of 498 deaths during the month of June, only thirteen were from small-pox.

—A committee has been appointed by the British Medical Association to investigate the effects of different occupations and employments on the physical development of the human body.

—The Government Health Reports state that Plant City, Florida, has again become infected with yellow fever. There were two deaths in June. Active measures have been taken to isolate the town.

—The Benevolent Fund of the British Medical Association has had large demands upon it, and its balance is very low. The *British Medical Journal*, July 7, makes an urgent appeal for subscriptions to the fund.

—The Paris authorities are now using coal-gas to kill the vagrant dogs which fall into the hands of the police. They are crowded into a closed box containing the gas, and in three or four minutes their dead bodies can be taken out.

—"The man without a larynx," who has been an object of curiosity to the Paris doctors for some time, recently died in attempting to remove, cleanse, and replace the canula in his throat himself, instead of going to the Saint Louis Hospital, as he had always done before.

—The *Boston Medical and Surgical Journal*, July 12, 1888, says that the Board of Health of New York City, on the 29th of June, appointed forty-one physicians for the special summer service of the Department. They are engaged for two months at a salary of $100 per month, and each physician is expected to spend at least eight hours a day in visiting the tenement-houses of his district. This work is under the direction and supervision of Dr. Moreau Morris.

HUMOR.

"MISTER," HE PLEADED, "I have lost a leg, and—" "Yes, so I see. It's mighty provoking to lose anything. I lost a dog once that I had often tried to give away, but I was mad about it just the same."—*The Epoch.*

"NO," SAID THE HOUSEMAID, "I don't apologize to a man when I throw a bucket of water down the front steps to wash 'em, and he comes along and gets drenched. I've tried apologizing, but I've found there's nothing you can say to a man in that case which will satisfy him."—*Scranton Truth.*

WIFE (WHO HAS THE FOREIGN-LANGUAGE "spasm"): "John, do you know, I'm getting on splendidly with my French. I am really beginning to think in the language." Husband: (interested in his paper)—"Is that so? Let me hear you think a little while in French."—*N. Y. Sun.*

FEARS RELIEVED.—Office-boy (to country editor): "Man outside, sir, wants to see the editor." Editor (anxiously): "What does he want of the editor?" Boy: "Says he wants to mop the floor with him." Editor (relieved): "Oh, show him in. I was afraid it was somebody come to stop his paper."—*Life.*

OBITUARY.

J. MILNER FOTHERGILL, M.D.

Dr. J. Milner Fothergill, whose name has become familiar to American readers through his books and his articles in medical journals, died June 28, of gangrene of the foot, which occurred as a complication of diabetes, from which he had been a sufferer for many years. He was born April 11, 1841, in the village of Morland, Westmoreland. His father was a physician, and so were several others of his ancestors. He was graduated from University of Edinburgh in 1865.

In 1872, he wrote his first book, on "The Heart and its Diseases, with their Treatment." This at once secured for him a wide reputation, and a second edition was published in 1879. His later writings were devoted for the most part to diseases of nutrition. He was a bold and fearless writer, and rather challenged than feared criticism. His style was graphic and racy, charming one almost into forgetting his faulty logic, supported as it was by dogmatic assertion.

Dr. Fothergill was married in 1880, and leaves a widow but no children.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled **Norwegian Oil,** rendering it by common consent the **Best Emulsion in the market.**

Clinical Lecture.

URETHRAL FEVER.

BY G. FRANK LYDSTON, M.D.,

LECTURER ON THE SURGICAL DISEASES OF THE GENITO-URINARY ORGANS AND VENEREAL DISEASES IN THE COLLEGE OF PHYSICIANS AND SURGEONS, CHICAGO, ILLINOIS.

(Reported by William Whitford, M.D.)

Gentlemen: The greatest discrepancy exists in the statements of various authorities with regard to the pathology of the polymorphous disease known by the various terms of "urethral, urinary, and urine fever." This I firmly believe to be due to the fact that these terms are applied in a haphazard manner to several distinct types of disease consequent upon diseases of, and operations upon, the genito-urinary apparatus; and I am positive that a careful survey of the clinical evidence upon the subject will bear me out in my opinion. Urethral fever, as the term is ordinarily used, is, so to speak, an omnibus which comprises a series of widely-varying phenomena following chronic disease or accidental or surgical trauma of the genito-urinary tract. Fallacious as the nomenclature of these phenomena may seem to be, we are compelled to select some term by which they may be recognized. The term "urine fever," as suggested by Reginald Harrison, is, perhaps, the most accurate. Unfortunately, however, even this term is suggestive only of one element which may act as a causal factor in the production of the morbid phenomena which we are about to consider. Harrison has adopted this term because of his opinion that the so-called urethral fever is invariably due to morbid changes in the urine at the site of injury, these morbid changes giving rise to the development of toxic materials, which, when absorbed into the circulation, are always inimical to health and often productive of a fatal result. Whatever the cause or causes of urethral fever—and this we will consider later on—the subject is one of the greatest practical importance to the surgeon, for the various phases of this disease constitute the principal danger of operations or injuries upon the urethra, prostate, and bladder.

From a clinical standpoint, I believe that we are warranted in dividing urethral fever into six forms, these forms, however, being capable of demonstration only in typical cases in each instance. They may merge one into the other, and are all secondary to genito-urinary operations, chronic disease, or injury.

1. This first form, which is by far the simplest, consists of a nervous rigor, which is not succeeded by fever, and which follows, within a comparatively short time, operations or injury. This nervous disturbance is, in all probability, due to slight surgical shock, with a resulting vaso-motor disturbance of the peripheral circulation.

2. Traumatic or surgical fever, due to the same causes, and dependent upon excessive reaction from surgical shock. This form of fever is quite apt to be modified by a varying degree of septic infection.

3. Toxicæmia following severe shock, with a resultant perverted elaboration of the urinary secretion and the formation of organic poisons similar to the vegetable alkaloids. Associated with this we have reflex inhibition of the functions of the kidney with its attendant uræmia. This we

may term the typical form of urethral fever. It is sometimes complicated by convulsions.

4. Classical septæmia, which may prove fatal within a short time, or may merge into the pyogenic form of septæmia (pyæmia), with its characteristic circumscribed and diffuse suppurations in the various organs and tissues of the body.

5. Chronic urinary fever attendant upon obstructive diseases of the urinary organs.

6. Cases of a mixed type, which combine in varying degrees elements of the first four forms of the disease.

If the above classification is correct, there is little wonder that the opinions of various authorities in regard to the pathology of urethral fever vary so widely. There must be some explanation for the fact that one authority claims that these varying phenomena are invariably septic; another, that they are due to ammoniacal decomposition of urine and subsequent absorption of the product; another, that they are due to simple uræmia; and last, but not least—and of this theory Reginald Harrison is the principal exponent—that they are due to obscure changes in the urinary secretion, and the formation of new, and as yet unisolated, toxic compounds. It is evident to every practical surgeon that none of these causes is sufficient to explain all of the cases of so-called urethral fever. Simple absorption of healthy urine certainly will not cause the disease, nor, as has been shown by Dr. Keyes, will it produce even simple suppuration when introduced into the cellular tissue by hypodermic injection. We do know, however, that urine in a state of decomposition is possessed of most powerful propensities for evil; in fact, there is hardly any organic substance with which I am acquainted that is so inimical to the vitality of cellular tissue. The experience of our best surgeons in cases of urinary extravasation will bear me out in this assertion. Now, there is a close resemblance between the effects of extravasation of decomposing urine and those of the poisons of erysipelas, of dissecting wounds, or even the bite of venomous reptiles, as far as their effects upon the vitality of connective tissue are concerned. It is obvious to anyone, who stops to consider for a moment, that there must necessarily be, in all cases of injury or operations upon the urinary organs, pronounced danger of septic infection. The injury, or the site of the injury, is usually such that free drainage is impossible. Decomposing urine is usually present, and is productive of more or less death to connective and cellular tissue, and there are always present the conditions of heat and moisture. Such an environment, as you doubtless are well aware, is peculiarly favorable to the development of those minute organisms upon which septicæmia is supposed to depend.

None of the explanations which have been given will, when taken alone, explain the fatal result which has been known to occur from the simple introduction of a smooth staff into the urethra.

There is also food for reflection in the fact that a single straight cut in the urethra—as, for instance, internal urethrotomy—is productive of less shock in many cases than is repeated stretching of the sensitive structures of the stricture by a sound or bougie. It is well known that an irritable, sensitive, and contractured tissue is much more safely and comfortably dealt with in any situation by a complete division than by attempts at stretching.

The cure of stricture by gradual dilatation is dependent upon (1) mere mechanical distension; (2) upon reactionary hyperæmia, with increased tissue-change at the site of the organic deposit. The functions of the lymphatics and veins are increased in activity, and absorption takes place very rapidly. It would appear, then, that if the tissue is extraordinarily sensitive, as is frequently the case in organic stricture, and if there are present toxic principles from decomposing urine, or ordinary septic materials at the site of the stricture or behind it, the operation of dilatation must necessarily be followed by a degree of nervous shock dependent upon the susceptibility of the individual and by a varying degree of absorption of noxious materials. The lymphatics and veins, unfortunately, have not the power of discriminating between the organic substances which are obnoxious to the welfare of the individual and those which can be disposed of in a physiological manner without injury to the blood or tissues, and they, therefore, take up the poisonous materials simultaneously with the products of retrograde tissue-change.

The relation of organic and functional disturbance of the kidneys to urethral fever is a most intimate one. There is probably no case of obstructive disease of the genito-urinary tract, of long standing, which is unaccompanied by functional disturbance of the kidneys, and, in a large proportion of cases, there occurs, later on, actual organic change in the renal tissues. This condition of affairs is to be anticipated and given serious consideration in every case of

chronic urinary disease. The immediate effects of the kidney-difficulty may not be marked, because of the activity of vicarious elimination by the skin and bowels, this vicarious action of these structures constituting the means by which the system accommodates itself to the imperfect elimination of the constituents of the urine. There are few, very few, persons, even among those who term themselves healthy, in whom the bodily sewage is absolutely perfect, and it is obvious that, when the kidneys perform their functions imperfectly, this condition of imperfect sewage becomes one of vital importance. When, as a consequence of operations upon the genito-urinary organs, surgical shock is produced, reflex hyperæmia of the renal tissue is quite apt to result. This produces a strain upon the kidney, which, in its impaired condition, it is unable to withstand, and as a consequence its functions are completely inhibited, with resultant uræmia.

The subject of autogenesis, in its relations to the development of certain constitutional diseases, demands more attention than is usually accorded it, and it is probable that researches in this direction, of a physio-chemical character, will, in the future, shed new light upon many diseases, the etiology of which is now obscure. Among the modern writers who have given considerable attention to the morbid results of perverted physiological chemistry, Benjamin Ward Richardson is perhaps the most prominent. It is to the researches of this author that we are indebted for the most widely accepted theory of the pathology of rheumatism. It is probable that perverted tissue-metabolism bears a causal relation to the typical cases of urethral fever. This perverted tissue-metabolism may quite readily be brought about by surgical shock. We know quite well that mental emotions of various kinds, and those impressions upon the nervous system which result in the condition that we term "shock," may produce marked changes in the physiological secretions of the body, these changes consisting either in an increased or diminished flow, or of obscure chemical changes of composition; thus we may have, through various nervous impressions, an increase or decrease in the quantity of the saliva, the lacteal secretion, the gastro-intestinal secretions, the urine, and of the menstrual flow.

A familiar illustration of the chemical effect of various emotions upon physiological secretions is the change in the quality of the lacteal secretion, induced by fright, anger, or grief. This change, although incapable of demonstration by microscopical or chemical research, is most pronounced in its morbid effects upon the child, cholera infantum of a most fatal character being a frequent sequel to the emotions of anger in the mother. Precisely what this change in chemical composition may be, is an open question; but it is possibly a species of decomposition which results in the formation of a poison analagous to the "tyro-toxicon" discovered by Prof. Vaughan in impure cow's-milk. It is well known that great care is necessary on the part of those who supply milk for the use of infants, to prevent fatigue and various sources of excitement in the cows. It is well known, too, that sexual excitement in a cow is productive of marked changes in the milk, and renders it unfit for human food. If these changes occur in one secretion, it is highly probable that all of the physiological secretions are susceptible to them. It is probably true, in the case of the saliva, that the emotion of anger causes the development of toxic principles in that secretion, and this may possibly explain the serious results that are so apt to ensue from the bite of an enraged human being. In the case of the urine, the influence of surgical shock may be inferred to consist in the development of organic poisons in that secretion. This, according to Reginald Harrison, may be considered to be hypothetically analagous to the ptomaines and leucomaines discovered by Selmi and Gautier, in both dead and living bodies, and which so closely resemble the vegetable alkaloids, particularly nicotine, brucine, and strychnine. The toxicæmia resulting from such changes would explain the otherwise obscure and mysterious cases of death following the simple introduction of a sound. In some cases the development of uræmia or toxicæmia is very gradual, and results from successive operations upon the urethra. The poisonous materials may accumulate in the system for some time and their presence fail to manifest itself until the system is, so to speak, ready for the explosion, when a previously tolerated and comparatively slight irritation of the genito-urinary apparatus will be sufficient to develop a serious result.

A competent surgeon, and one of my personal friends, had performed urethrotomy upon an apparently healthy young man of 28 years of age. The stricture was located about three-quarters of an inch posterior to the meatus, and was divided under cocaine without any difficulty or pain whatever.

A sound was passed every second day thereafter, each operation being preceded by the injection of a four per centum solution of the muriate of cocaine, the quantity used being about two fluiddrachms. About a week after the urethrotomy, the patient complained of considerable nervousness and insomnia; but this was not considered of any particular importance. On the ninth day, an attempt was made to perform the usual operation of sounding and injection of cocaine, the patient meanwhile lying upon an ordinary surgical chair. The doctor left the patient for a moment, to obtain his sound and to give the cocaine an opportunity to affect the urethra. He was called back in about a minute by the patient, who complained of dizziness, and immediately fell back on the chair in convulsions. Assistance was called, stimulants were given, and the galvanic current used, but without avail, the patient dying in something less than five minutes. At the post-mortem, a thorough examination of all the vital organs was made, but everything was found perfectly healthy, with the exception of the kidneys, which were so extremely congested that they presented a bluish appearance similar to that of the spleen. This fatal result was surely not attributable to the cocaine, but was evidently due to the sudden explosion of poisonous material which had been gradually accumulating in the system as a consequence of imperfect action of the kidneys, and the metabolic action of slight surgical shock upon the tissues. This condition of toxicæmia gradually grew more pronounced, and finally was so severe that a comparatively slight irritation was sufficient to inaugurate a nervous explosion. Such an irritation was afforded by the mechanical effect of the injection of cocaine, and it is probable that the introduction of simple water would have had a similar effect.

The danger of the development of urethral fever is directly proportionate to the depth of the distance of traumatic and surgical injuries of the urethra from the meatus. Those situated in the pendulous portion of the urethra are not, as a rule, very dangerous as compared with those situated in the fixed or deep portion of the canal. The explanation of this is very simple, the nerve supply of the deep urethra being much more abundant and sensitive, the cellular tissue more abundant, and the opportunities for drainage much less favorable than in the pendulous urethra. Decomposing urine is less apt to remain behind a stricture in the pendulous portion of the canal than in the deep portion, this being due to simple gravity and to the fact that strictures of this portion of the canal are usually of large calibre. Urinary extravasation in the pendulous portion of the urethra is not apt to produce serious danger to life, inasmuch as the connective tissue in this situation is very sparse and the extravasated fluid is likely to be detected before it is has burrowed back into the perineum.

The clinical features of urethral fever in its various forms require some special consideration. The nervous form of the disease usually appears in patients of an impressionable constitution, or who, in other words, present a decided tendency toward neurotic disturbances. Oftentimes its occurrence may be anticipated by the behavior of the patient while he is under instrumentation. He is quite apt to have nausea, perhaps vomiting, slight rigors, partial or complete orgasm, or more or less complete syncope during the introduction of instruments into the deep urethra. Such patients are apt to develop, as a rule, within twenty-four hours after urethral operations or injuries, a sharp chill. This lasts for a variable time, being rarely prolonged, and then disappears, leaving the patient about as well as before, with the exception perhaps of more or less nervous depression. Rarely, indeed, there may be a slight amount of fever or sweating.

The traumatic form is the most common; it manifests itself by a sharp chill, usually within twenty-four hours after operations or injuries of the genito-urinary tract, and is followed by pronounced fever and sweating. The disturbance either passes off after a single paroxysm, or is followed by a period of general malaise, with perhaps a recurrence of the paroxysms for several days. In these latter cases, there is present in all probability a slightly septic element.

The third form (the typical form of the disease) may or may not be attended by a violent chill coming on within twelve to thirty-six hours. There is marked prostration, violent vomiting and diarrhœa, coldness of the surface of the skin at first, succeeded by more or less febrile elevation of temperature later on if the patient survives, with suppression of urine, merging in a very short time in fatal cases into coma of an apparently uræmic type. I say "apparently uræmic type," because, according to the theory I have advanced regarding the action of shock upon the urine, there is probably in many cases a toxic element present independent of uræmia. Cases of this kind may come on gradually and mani-

fest themselves by a sudden explosion in the form of convulsions, as is illustrated by the fatal case that has just been related to you.

The fourth or septic form of urethral fever manifests itself usually by a slight (but sometimes by a very severe) chill; this is followed by fever of a varying degree of severity. The patient may sink into a typhoid condition, or become comatose, and die within from two to ten days from acute septicæmia, or the condition may be subacute and merge into the pyogenic form of septæmia, known more familiarly as pyæmia, in which event the patient finally succumbs to the slow development of circumscribed or diffuse purulent deposits in the joints, viscera, and other structures of the body.

The fifth form of urine fever may be described as a chronic condition of toxicæmia and nervous irritation produced by long-continued obstructive and inflammatory affections of the genito-urinary tract. This condition of toxicæmia and general nervous irritation is one which is not generally recognized, but which is very important in its relations to chronic genito-urinary disease. It exists in the majority of cases of organic stricture of long standing, in old men suffering with prostatic hypertrophy, in tumors of the bladder, in chronic cystitis from whatever cause it may arise, and in pyelitis, particularly the form due to the presence of nephritic calculi. There is a marked tendency in patients suffering with these affections to a mild form of hectic fever; flushings of the face, with slight elevation of temperature and perhaps followed by a certain degree of perspiration, are quite common; nervous irritability is especially marked. Indeed, there are few diseases which are productive of so much mental depression and of so much irritability of temper as chronic diseases of the genito-urinary tract. The old man with a vesical calculus or prostatic hypertrophy, or, for that matter, the young man with a stricture, is apt to be unreasonably morose and irritable. In all of these cases, there are apt to be present more or less obscure rheumatic or neuralgic pains in various situations. After prolonged retention of urine from any cause whatever, you will find that the majority of patients will suffer for a few days or weeks from more or less marked elevation of temperature. These different general conditions are due, in my opinion, to toxicæmia which is dependent upon (a) imperfect elimination of the products of retrograde tissue-metamorphosis, (b) to a greater or less degree of absorption of morbific materials produced by inflammation and the decomposition of residual urine behind the site of obstruction. You will find that many patients suffering from chronic genito-urinary disease of an obstructive or chronic character fail to realize how sick they are until the diseased condition has been removed, or at least greatly improved. They then find that slight disturbances to which they had paid comparatively little attention, and which they had never dreamed of attributing to their urinary trouble, have disappeared. This is due in a great measure to the fact that reflex nervous irritation has been relieved; but, more than this, it is due to the fact that the constant absorption of poisonous materials from the site of disease or above it no longer occurs.

I have designated a sixth or mixed form of the disease. It is probable that you will meet with comparatively few cases that cannot be assigned to one or the other of the first five forms of the disease that have been described, but occasionally cases will occur in which there are, for example, equally strong evidences of septic disturbance and of uræmia, with possibly a tendency to disturbance of the nervous functions.

The principal measures of treatment of urine fever are of a prophylactic character, for, unfortunately for the patient, the marked forms of the disease are seldom recovered from. The principal feature of prophylaxis should consist of strict attention to those principles laid down in the lecture on "Genito-urinary Hygiene." If the functions of the kidney are stimulated by alkaline diuretics, and the skin and bowels kept in an active condition, thus affording vicarious relief to the kidney, the patient is placed in the best possible condition to avoid those complications which we have described. In addition to these measures, moderate doses of antiseptic drugs may be given internally. Of these, I prefer boracic acid in ten-grain doses, as recommended by that excellent authority, Professor Palmer, of Louisville. Salicylic acid, or preferably the salicylate of soda, is also an admirable remedy. Local antisepsis in cases of chronic bladder and prostatic disease is of course essential, and can be accomplished by irrigation with mild antiseptic lotions, such as carbolic acid, borate of soda or boracic acid, and the bichloride of mercury. You should avoid operating upon cases complicated by structural renal disease if it is possible to do so, and, if an operation is unavoidable, you must be careful in your

manipulations; but you should throw the responsibility of your results entirely upon the patient and his friends. Prior to operative interference, particular attention should be paid to the urine and to local antisepsis. The patient should be put to bed and instructed to remain perfectly quiet; he should be placed upon a milk diet and moderate doses of quinine—5 grains, three times daily, for from a week to ten days previous to the time appointed for the operation, being about the required dose.

Various drugs have been recommended for administration just before or at the time of urinary manipulations or operations. Quinine and morphine in doses of ten grains and one-quarter grain respectively are the most popular remedies, and unquestionably have an excellent effect by increasing the resisting power of the nervous system and thus lessening the liability to shock. Jaborandi is also recommended for the same purpose, and, inasmuch as its physiological action is such that it must necessarily relieve any strain upon the kidney, this drug seems to me to be one of our most philosophical remedies. The muriate of pilocarpine may be given instead of the fluid extract of jaborandi, or the muriate of pilocarpine, in hypodermic doses of a fourth to one-half grain, instead of jaborandi; and, in case uræmia supervenes, this method of administration is absolutely essential.

The milder cases of urine fever (the nervous and traumatic forms) are rarely fatal, but may possibly lead to the severer forms of the disease, and consequently require our attention. The administration of opium and jaborandi, with perhaps (in the traumatic form of the disease) aconite or veratrum viride, constitutes the best measures at our command. In the uræmic form of the disease, our attention should first be directed to the vicarious elimination of urea, for we can waste no time in attempting to restore the functions of the kidney within the first few hours after the supervention of the uræmia, especially if coma has occurred. Pilocarpine will act upon the skin, even when the patient is in a comatose condition, and it should be given freely. The bowels should be moved by croton oil, two or three drops of which, in combination with five or six drops of olive oil, may be placed upon the back of the tongue. If the patient is able to swallow, elaterium in doses of from one-eighth to one-third of a grain is preferable to all other hydragogue cathartics. Hot baths should be given, and dry or wet cups applied over the region of the kidneys. Digitalis may be given internally as a diuretic after the emergency is over, but it would be a waste of time to attempt to accomplish anything by diuretics before vicarious elimination of urea has been attended to.

When the septicæmic or pyæmic form of urine fever develops, very little can be done in the majority of cases beyond supporting the powers of life by free stimulation, a fatal result being almost inevitable. It is, however, in my opinion, our duty to attempt to avert a fatal result by incision and drainage, where possible; and, if the case is clearly septic, a free incision at the site of the stricture, or a perineal cystotomy in cases of bladder and prostatic trouble, constitutes the proper surgical procedure.

The management of cases of chronic urinary fever consists in local antisepsis by irrigation and the removal as soon as possible of the organic condition upon which the gradual and constant septic infection depends.

SMALL DOSES: THERAPEUTIC CONSIDERATIONS.

BY JOHN AULDE, M.D.,

DEMONSTRATOR OF PHYSICAL DIAGNOSIS IN THE MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

(Continued from page 841.)

Electricity.—Proofs are not wanting that electricity, either in small or large doses, is a paralyzer, although the opponents of this theory insist that, given in medicinal doses, it is a nerve stimulant; but the latter view is based on a "temporary hypothesis," while the former is founded on facts. That there exists a diversity of opinion concerning this valuable agent in the treatment of various disease-conditions may be accounted for on the ground that the theory of the action is too intimately associated in the mind with the theory of the effect. The philosophy connected with the action of electricity is one thing, the physical or molecular changes incident thereto being taken as a cause, while the effect must be looked upon as a separate and distinct condition, representing an entity in itself.

Having arrived at this healthy understanding, we are prepared to estimate the various phenomena manifested by an agent

so universally applied. Taking our cue from Dr. Brunton, who says: "Slight electrical shocks from a coil increase the rapidity of the protoplasmic movements; stronger ones cause tetanic contraction" (*Phar., Ther., and Mat. Med.*, p. 46), which may be accepted as a demonstration of the proposition that electricity is a paralyzer. But, if more evidence were needed, we have it on the following page: "A constant current of electricity causes contraction and imperfect tetanus," referring of course to its action and effect on protoplasm. Now, what is the relation existing between the protoplasm and nerve and muscular tissue? It is well known that in the lower forms of life we are unable to differentiate between the nervous and the muscular tissue, so intimately are the two blended, their inter-relations being mutual; but, as we ascend in the scale, there is found a distinct and important difference, the inter-action and inter-relations of which will be referred to more particularly when I consider the subject of strychnine.

These experiments, along with the investigations of others, furnish sufficient evidence to warrant the following conclusions:

1st. That electricity is not only a protoplasmic poison, but also a paralyzer of nerve-function.

2d. That small doses, mild currents, increase the rapidity of protoplasmic and muscular movements, and

3d. That large doses, powerful currents, lessen the rapidity of protoplasmic and muscular movements, and, continued long enough, produce tetanic rigidity.

4th. That, by paralyzing nerve-function, control or restraining power over muscular irritability is lost in direct ratio to the strength of the electric current.

5th. The action of this agent is, therefore, always the same, only different in degree.

6th. The effect of the electric current depends upon the size of the dose—mild or strong currents—and the muscles supplied by enfeebled nerves, as a rule, will be first to respond to this influence.

The truth of these deductions is forcibly illustrated in the treatment of lumbago by the Faradic current, one of the most efficient remedies we have for this affection. These cases are observed in patients subject to the rheumatic or gouty diathesis, and generally appear shortly, or at times suddenly, after exposure to cold, damp, or inclement weather. A mild current properly applied for the period of from ten to thirty minutes will almost invariably relieve the pain, and frequently a single application will be sufficient. Much will depend on the nutrition of the patient, and whether the attack is acute or of long duration, and strong currents may be used to produce the same effect; but my observations lead me to conclude that the milder currents are to be preferred, as they cause less pain, and there is not the same depression following their application. The same method will be found effective in the treatment of contusions and in other affections of like character, and, while they afford relief and effect a cure, they really do nothing more than anticipate nature in the work. The *modus operandi* will be considered under the head of *remarks*, at the close of this paper, and, taken in connection with the study of strychnine, I trust we shall have a better knowledge of the action and the effects of small doses.

Strychnine.—The investigations of Brunton have shown that, in the experiments to determine the irritability of muscle, there is an interval between the application of the so-called stimulus and the contraction of the muscle, called the latent period. In connection with these observations is the statement, also, that the latent period is shortened by small doses of strychnine, while large doses lengthen it, which accords with the views already advocated in this paper, viz., that the action of a remedy is always the same in health, but the effect is modified by an increase or diminution of the dose. This statement can be misleading only when the circumstances and conditions attending the observation have been modified by influences already noted.

We have here, then, an illustration of an important general principle underlying the application of drugs to determine their physiological action, as well as a delicate indication for the selection of appropriate remedies in the treatment of disease—a principle which will be more fully understood when we consider the action and effects of ergot. But the work of Dr. Brunton does not end here, as he has placed himself on record concerning the manifestations of both nerves and muscles under the influence of various poisons, strychnine included. The action of the latter is admitted to be that of a nerve paralyzer, and when given in sufficient quantity ("action continued long enough") the resultant effect upon nerve and muscle is tetanic convulsions. A quotation will more fully demonstrate the views of our author: "In some cases the nerve is affected so much before the muscles (by poisons)

that at first sight it might appear that the nerve alone was paralyzed, and the muscle left unaffected.''[1]

Dr. Brunton is a painstaking and faithful observer, but, by a process of induction not warranted by the facts, his conclusions are sometimes barren of the therapeutic possibilities which ordinarily we are led to anticipate. Thus, he says: ''Strychnine stimulates the spinal cord, . . . and, if the action continue long enough, . . . will ultimately cause paralysis of both spinal cord and motor nerves.''

From what has been said, we may conclude that strychnine should preferably be given in small doses, the reasons for such a course being easily formulated:

1st. Because it shortens the latent period of muscular irritability, thereby increasing the circulation and improving the nutrition of the tissues.

2d. Because the remedy is more evenly distributed throughout the system, and the muscles supplied by enfeebled nerves, being bathed in the blood containing it in solution, are constantly under its influence.

3d. Because it reduces to a minimum the dangers of tetanic rigidity and convulsions.

As an objection, it may be urged that small doses would scarcely be appreciated, and that they would fail for lack of power to saturate the circulating fluid; but such opposition is refuted by the experiments of Magendie, a detailed account of which will be omitted. It will be sufficient to recall the following facts: when injected into the pleura, the poisonous effects of strychnine were perceived almost immediately, and within twenty seconds when introduced into the peritoneum. Absorption from the mucous surfaces was less rapid, but the effect was the same. The well-known diffusibility of strychnine, 1 part in 1,280,000 parts of water being perceptible to the taste, gives this drug unusually distinctive characters as a subject for study.

As the present paper is mainly intended to call attention to certain general laws, no attempt will be made here to outline a complete working theory, and I may close with some suggestions, therapeutic in character, which are in accord with the views set forth.

Small doses of strychnine have lately been recommended for the relief of insomnia due to exhaustion, a condition often found in those who are engaged in literary work. It is assumed that a person who gets too tired will be unable to sleep, and that, if several small doses of strychnine are taken shortly before bed-hour, this feeling of exhaustion will be relieved and the patient left just tired enough, when Morpheus, the changing god of dreams, will gently lull him to slumber. This method I have found far superior to the use of the bromides or chloral, while its simplicity and practical value commend it to every practitioner. The plan I have adopted is as follows: About half an hour before retiring, let the patient dissolve a tablet containing the one one-hundredth of a grain of the sulphate in six teaspoonfuls of water, directing that a teaspoonful be taken every five minutes until the whole is taken. The results of this treatment will be a great surprise to those who have not considered the matter, and are well calculated to demonstrate the principle for which I would contend. In the treatment of many slight gastric affections, a similar plan will be found equally satisfactory. By ''slight gastric affections'' are meant those cases in which apparently there is little demand for medication, but still are of such a character that the subjects are necessarily compelled to undergo no little uneasiness, such as slight dyspepsia, and frequently those cases resulting from sympathetic derangements, as in the case of the vomiting of pregnancy. The latter is often very effectively treated by adding, to a glass of water, from ten to twenty drops of nux vomica (tincture), directing that, in the early morning, a teaspoonful be taken every ten minutes for an hour, and, after the first hour, the same dose may be continued at intervals of one or two hours. In the treatment of ordinary simple dyspeptic conditions, such as that just mentioned, a solution of the same strength may be prepared, and the patient directed to take a teaspoonful before and after meals. The same plan is very useful in the case of those suffering from a debilitated condition of the system, and may be advantageously adopted as an adjuvant to other treatment.

Remarks.—A few words should be added here as to the value of these generalizations, and the bearing which they may have in the elucidation of the theory of the actual value of small doses in the treatment of disease. As to strychnine, for example, its value is well recognized, but the method by which we arrive at results are not so well understood, the deductions of experimental physiologists being somewhat contradictory and misleading. Its application in the cases above mentioned is accounted for on the

[1] *Loc. cit.*, p. 119.

basis of its physio-pathological action, or, to be more plain, its physiological action in the presence of pathological changes, involving, we may presume, certain modifications in the cell-action. Whether the tissues are normal or abnormal, we always have to do with the cell-action, and, when a medicament is added, we have as a resultant the cell-action and the drug-action, and we may assume that, when the latter is properly applied, the drug-action is in the nature of a complementary action to that of the cell. It is certainly not "substitutive" action, nor does the expression "elective action" sufficiently cover the ground, while, in the light of these investigations, both homœopathy and dosimetry are altogether irrelevant expressions. Neither can it be called specific, for but very few remedies are confined to any specific effects, at least not in the treatment of disease. As I do not feel at liberty to decide upon the matter at present, we may conveniently submit the matter to a medical linguist like Dr. Campbell, or a nosographer such as Dr. Gouley.

In closing the discussion, it does not follow that the subject has been exhausted, for only three remedies have been considered, and in a most superficial and hasty manner; but, if what has been said will serve to cast a single additional ray of light upon an intricate and interesting matter of the utmost importance to physicians and to humanity, I shall feel that the task has not been undertaken in vain. I venture the assertion that there is not a remedy in the whole materia medica which is not entitled to a restudy upon the plan which I have somewhat faintly outlined, and doubtless the physician of the future will be able to understand the difference between drug-action and drug-effect; he will be competent to point out where the action ends and when the effect begins. The therapeutist of the future will be he who reads aright the value and the application of small doses, and who, with but few remedies, has learned to know them well. An apt quotation from Dr. Campbell will suffice: "For many an hypothesis supported by the ablest of physicians has disappeared from the pages of our medical books, leaving only a few words, like fossils, to tell future generations the story of their rise and fall."

4719 Frankford Avenue.

—Beginning with the session of 1888-'89, the College of Physicians and Surgeons, New York, will require a three years' course of study from its students.

FOOD AND DYSPEPSIA.[1]

BY GEORGE N. HIGHLEY, M.D.,
CONSHOHOCKEN, PA.

The subject to which I invite your attention for a few minutes is one which I fear the most of you will think somewhat dull, though I doubt if any will deny its importance. Indeed, when one considers the large percentage of people who are sufferers from this malady, either as a complication of other affections or as a disease *per se*, the wonder is that so little attention is given to it.

Dyspepsia is impaired digestion: digestion is a process of solution by hydration. Food necessarily exists in the vegetable world in an insoluble form, otherwise the rains would soon return it to the soil. To convert the insoluble food into a soluble form is the prime object of the digestive process. How is this accomplished? Liebig's division of foods into proteids, carbo-hydrates, and fats seems to be the most natural one, and is the classification most generally accepted at this time.

The food in passing along the alimentary canal comes in contact with the following juices, viz: The saliva, gastric juice, bile, pancreatic juice, and others whose properties are either unimportant or little understood. So far, experimenters have proved almost beyond cavil that the saliva converts the insoluble starch into the soluble grape-sugar; that the gastric juice changes the insoluble proteids into the soluble peptones; that the bile and pancreatic juice render the fatty foods more soluble; and that the pancreatic juice alone is capable of effecting all these changes. However, in order that these changes may be fully and easily accomplished, it is necessary that the food shall have undergone some preliminary treatment, which mainly consists in tissue-disintegration. This is accomplished by cooking and by mastication.

Had civilized man the peptic powers of some of his four-handed cousins—as for instance the Ceboo monkey, which is said to be able to eat its own weight of bananas in the twenty-four hours—he might ingest his food in any manner and quantity he saw fit, without impairing the digestive process. But, while a few seem to be able to digest or void whatever they can ingest, the majority must eat food properly cooked and masticated, or suffer the tortures of

[1] Read before the Montgomery Co., Pa., Medical Society.

indigestion. The part which mastication plays in comminuting the food and mixing it with the saliva is so obvious that mere mention of it is sufficient.

I ask your attention a little more fully to the changes wrought by cooking. First, as to its effect upon farinaceous foods. The starch corpuscle, which is the component part of this class of foods, is made up of an outside envelope, cellulose, and an inner part, granulose. Now, while the salivary secretion is quite active on the granulose, readily converting it into grape-sugar, it is unable to act on the cellulose. Hence the digestion of raw unboiled starch is attended with considerable difficulty. In the process of boiling or cooking, the cellulose coat is ruptured, exposing the granulose, and in this state the saliva has ready access to it. The cooking of animal foods, so as to promote their solubility to the greatest possible degree, requires considerable skill. Bad cooking augments their insolubility rather than their solubility. This will be best understood by observing the effect of ordinary methods of cooking upon the several constituents of meat. A piece of lean meat, as you all know, is composed of albumen, gelatin, and fibrin, closely related in their chemical composition and properties; kreatine and kreatinine, to which the stimulating properties of the meat are due; besides a small quantity of mineral salts, very necessary to tissue-nutrition.

As the white of the egg is a typical example of nearly pure albumen, we may see how it is affected by cooking. If we heat some white of egg in a test-tube into which a thermometer has been previously placed, we will find that, at a temperature of 134° F., white fibers begin to appear within it. These gradually increase until the whole mass becomes solid, which it does at a temperature of 160° F. The albumen thus solidified is tender, delicate, of a jelly-like consistence, and easily digestible. If now we increase the heat up to 212°—the boiling-point of water—keeping it there a short time, the coagulum will become shrunken, hard, and horny. Upon further elevation of temperature, it is converted into a substance so hard and tough that it may be used as a cement.

This simple experiment will show at once the difference between an egg which has been cooked by immersion in boiling water and one cooked at a temperature not exceeding 180° F. Even in the orthodox method of putting the egg into boiling water for three and a half minutes, it will be found that a part of it is quite hard, while other parts are semi-raw and slimy. If the same egg had been put into water at a temperature of about 188°, and allowed to remain ten minutes or more—time not so important, as it will not become hard even in ten hours—it would be found evenly cooked throughout. Practically, this can be done by putting the egg into at least a pint of boiling water, immediately setting it off the fire, and allowing the egg to remain in the water ten minutes.

Gelatin is said to form one-half the whole body, or, more correctly, perhaps, one-half the whole body is convertible by boiling water into gelatin. The tissues thus convertible into gelatin are tendons, sheaths of muscles, etc., and the cell-walls. Gelatin is a semi-solid tasteless substance, readily soluble in water at a slight elevation of temperature. Prolonged boiling and drying convert it into glue. The properties of fibrin, so far as cooking is concerned, are similar to those of albumen and gelatin. It is coagulable like albumen, and soluble like gelatin, though to a less extent. From what has just been said, it is evident that, whatever may be the method of cooking, temperature is an important consideration. A temperature sufficient to convert the albumen, gelatin, and fibrin into their most soluble condition is the desirable point. If this be exceeded, their solubility is lessened rather than augmented.

Retention of natural juices is another important point, not only to promote solubility, but also to preserve its nutritive and sapid qualities. If boiling be the method of cooking, the meat should be immersed at once into boiling water and kept there for a few minutes, or long enough to give it an insoluble coating of coagulated albumen. This will retain the juices, after which the cooking may be continued at a lower temperature. In roasting and grilling, we have not only to guard against excessive temperature, but also evaporation. If this be not prevented, we will have desiccated rather than cooked meat. This is a most common error of cookery; lately, however, patent roasters have been put upon the market and widely sold (at least in this vicinity), which fulfill the indication.

In stewing, the object is to have as much of the meat dissolved in the cooking medium—the water—as possible; hence it should be immersed in cold water and the temperature *slowly* raised, so that the early coagulation of albumen may not arrest the escape of the juices.

Frying is an operation practically impossible to the average cook, if the principles here laid down are carried out. Time forbids my going into the details of the several methods of cooking, and I must, therefore, content myself with these few general hints.

Our means of aiding the digestive process within the body are exceedingly limited. Beyond affording temporary relief with drugs, which irritate the coats of the stomach, causing a little extra flow of gastric juice (and these fail with repetition), or with pepsin, pancreatin, and the like, which digest small quantities of food, we are powerless to act. Far greater is the aid which we can render digestion by a careful selection of food, and having it properly cooked and masticated. Of not a little importance, likewise, is quantity. No more food should be ingested than can be readily assimilated. The Bushman who, in the twenty-four hours, can eat two dozen pounds of hippopotamus liver, a bucketful of broiled marrow, besides whole handfuls of peanuts and hackberries, is not so much more disgusting than he who goes to the evening reception and overloads his stomach with fried oysters, croquettes, lobster-salad, five or six varieties of ice-cream, besides cakes, coffee, ice-water, and numerous other articles. Intemperance in eating is to be as carefully avoided as intemperance in drinking.

In health, the appetite is a faithful exponent of the demands of tissue-nutrition. The dyspeptic has, however, more often a morbid craving for repletion, which must be carefully guarded against.

The important points, then, to be considered in connection with dyspepsia, are the quality of food, the quantity, cooking, and mastication. If these are properly attended to, we would have little need of medication.

THE MANAGEMENT OF CASES OF ABORTION.

BY STANLEY M. WARD, M.D.,
ELLENVILLE, N. Y.

The term abortion is used throughout this article to indicate the expulsion by the pregnant uterus of its contents prior to the seventh month of utero-gestation. Between the seventh and ninth months, inasmuch as the process of expulsion approximates so closely to labor at term, I think premature labor is a better term to apply.

As a rule, the nearer the fœtus has reached the seventh month of its intra-uterine life, the more pain the mother will undergo during her labor, but the less will she be exposed to the dangers of hemorrhage. The opposite of this rule is also true.

Of course, it is the duty of every physician to endeavor to thwart the efforts of the pregnant uterus when it attempts to expel its contents prematurely; but, in a majority of cases, after the woman begins to experience the pain of uterine expansion, let there be never so little flow, his efforts will be in vain. In a certain number of cases, we find something like the following to deal with: Some pain and hemorrhage, elongated cervix, rigid os, slight rise in body-heat, nausea, and vomiting. If we are morally certain that abortion is about to take place, our efforts should be directed toward hastening that event, and we should endeavor to empty the uterus as quickly as is compatible with the safety of the patient. A hypodermic injection of morphia, with a hot vaginal douche of some antiseptic solution, is administered, and the woman put to bed. After waiting from half to three-quarters of an hour, we make another vaginal examination, and our future treatment is largely guided by the result of that and the length of time the woman has been pregnant. If only for six or eight weeks, we shall not expect much of a product of conception, and the os uteri will not dilate much. The danger will be from hemorrhage, and later on from septic troubles should the uterus not be thoroughly cleared. The one thing *not to use*, no matter how severe the bleeding or how faint the pains, is ergot. A good many practitioners do use it, as I am aware, and a good many have trouble, as I have cause to know. A tampon made by winding a piece of asepticized cotton firmly and strongly with stout thread can be packed into the vagina, pressed firmly against the os, and we are masters of the situation. If the symptoms are urgent, it behooves us to stay with the patient; if not, we can leave, calling again in six to ten hours, when we shall probably find the contents of the uterus coming in good shape on the removal of the tampon. If not, the treatment may be continued by inserting another; and, if the patient is nervous and excitable, a fifteen-grain dose of chloral hydrate may be given if the stomach will allow it; if not, double the quantity by the rectum or an hypodermic injection of morphia if the physician prefers. After having satisfied myself that the uterus has been completely emptied, I am in the habit of ordering a douche twice daily of some antiseptic solution, and usually place my patient on

quinia and ergot—two grains of the former made into pill-mass with a half-grain of the so-called ergotine—thrice daily for a week. Cannabis Indica makes a valuable addition to this pill if there is a nervous disposition or if the patient is inclined toward melancholia, as sometimes happens. Thus I would manage an abortion happening early in fœtal life. Later on, as I have said, the treatment approximates toward that of labor at term. In any case where dilatation is slow, whether hemorrhage is severe or not, I use the tampon with the greatest faith and confidence. Equally am I certain that the use of ergot is productive of harm. I have seen the os uteri close up under its action time and again. The physician is often called to see patients whose history is something like this: A woman, after having had cessation of menses for three or four months, morning sickness, enlarged breasts, etc., begins to be "unwell." She wears a napkin, thinking herself about to menstruate. For a few days, the flow is slight, accompanied with some pain; suddenly, while at stool or while lifting, a great gush of blood comes from the vagina; with difficulty she reaches her bed, the practitioner finds her exsanguinated, pulseless or nearly so, flowing profusely. She may be unconscious. He gathers a little history, but there is no time to go much into the minutiæ. The first step is an examination. The os is somewhat dilated, the vagina filled with clots. He removes these and applies a tampon and administers restoratives. He should not give ergot unless he can be sure, which from the nature of the case he cannot be, that the uterus is empty; if he does, the flowing may stop, to be sure; but the uterus will contract, and he is only exposing the woman to danger in the future. I have seen such a case, in which ergot was used freely, the patient rallied from the profound syncope, and the hemorrhage stopped; but she bled for a month in varying quantities, at times profusely, and it was only after a bit of the placental membrane had been removed that it ceased. In the case I have ventured to portray, as soon as reaction has taken place, the physician must look for the offending substance. In the majority of cases, it can be easily found and removed, frequently with the fingers or dressing-forceps. If the tampon is applied thoroughly, it controls the hemorrhage and helps dilate the os uteri. This is an entirely different state of affairs from a case of *post-partum* hemorrhage at full term labor. In the one case, we have a greatly enlarged uterus which we know to be thoroughly emptied—our efforts are all directed toward closing it; in the other, a uterus not enlarged to any great extent, its condition we do not know, though we presume it to be only partially empty—our effort is not to close it and so shut up within it the very thing that is causing the damage. Of course, the physician is expected in such a case to remain with his patient, and not to leave her until all danger is past; and all danger *is not past* until the bit of placenta or whatever it may be is removed and the uterus thoroughly contracted If necessary, a dull curette must be used and the interior of the uterus scraped; but such measures are rarely necessary if the physician treats the case properly. I have assumed in the above that the physician, in making his first examination, fails to find within easy reach any substance that might be the cause of the hemorrhage; if he is so fortunate as to find anything, he of course should remove it, the quicker the better; and, as before stated, if he is now *certain* that the uterus is cleared, he may use ergot either by the mouth or hypodermically, preferably the latter.

A word or two about the method of using this drug: I have given the normal liquid ergot, Squibb's and Wyeth's fluid extracts, time and again by means of the hypodermic syringe, and never saw an abscess result. I usually give a half-teaspoonful at a dose. I administered during one night six such doses, to a woman who was flowing profusely and unable to swallow, and did not have a single bad result.

There is still another class of cases in women who have aborted; this is made up of those who have had bad treatment, viz., ergot administered at an improper time, and thus part of the products of conception have been shut up within the uterine cavity; and also of those women who, commencing to flow after an amenorrhœa of several months, are uncertain as to whether or not they have aborted. This is a difficult class of cases to treat. There is, on the one hand, the natural disinclination which the patient feels to having her uterus dilated, and, on the other, the uncertainty which, in the light of the imperfect history that most such cases give, the physician has as to just what proceeding will relieve the woman most safely and quickly. One patient consulted me for malaria, giving an excellent history of intermittent fever; but she incidentally remarked that she was not "regular." A little further questioning disclosed the fact that she had aborted. The malarial symptoms were septic from retained mem-

branes, and a dangerous hemorrhage, occurring within thirty-six hours from the time I first saw her, made the case clear. I removed some fragments from the uterus, and washed out the cavity with warm sublimate water. The malaria vanished, and she made a good recovery. In this case, I was saved the labor of dilating the uterus, as nature did it for me, as she will in a certain number of cases; but, where this does not happen, and such symptoms come on, symptoms which can be interpreted in only one way, dilatation by tupelo or sea-tangle tents, with a tampon thoroughly aseptic, must be resorted to. When dilatation is as complete as is necessary, a weak solution of iodine, sublimate, or carbolic acid may be thrown into the uterus, with the hope that the offending matters may be washed out; if this hope is not realized, a dull curette should be employed. There are some of the leaders in the obstetric world who advocate a greater reliance on the natural powers, in the meantime using rest, opium, quinine, and ergot with vaginal injections, to accomplish the desired result. I trust that I am as conservative in the treatment of these cases as the safety of the woman will allow; but, after all is said, some cases will fall into our hands in which radical measures must be employed. We should always give nature a fair field and all the chance in the world; but it may well happen that, while waiting to see what she can do, we lose our golden opportunity, and, when too late, attempt to do what, a few days before, could have been done just as well and with far different results. I believe, too, that if, within a few days of the time we may suppose the woman aborted—speaking now of those cases in which it is difficult to say from the symptoms and history whether or not such is the case—we dilate the os uteri and wash out the cavity, we shall be spared the use of harsher means. One thing, especially in this class of cases, it is absolutely necessary to get—the confidence of the patient; with this and the ability to interpret correctly what we see and hear, with a cool head and some tents, dull curette, tampons, a placenta-forceps, a good syringe, and an antiseptic, we shall seldom if ever fail to relieve our patient.

—It is announced, from Maysville, Ky., that a child recently born there has no arms, but a protuberance extending a few inches from each shoulder and terminating in the fingers. Its legs are said to be very short and stubby, and to turn backward.

MANAGEMENT OF THE NEW-BORN CHILD.

BY A. ADY, M.D.,
MUSCATINE, IOWA.

Late articles in the REPORTER remind me that I have some peculiar notions about the management of new-born children, and I would like to communicate them to your other readers. In the first place, I never allow anything made of wool to be worn next to the skin; let it be ever so soft and fine, it will tickle and irritate the cuticle of some little ones and make them cross and fretful; then come catnip and other remedies for colic, and in a short time something does ail the baby. Having often seen fretful babies made good and quiet by the removal of such clothing, it is the first thing seen to when consulted in such cases.

My favorite apparel for a first dressing is a cotton-flannel slip, and diaper of the same material (soft side next to the skin); nothing more—no bands, no skirts, nothing to punish the little fellow. After this simple toilet, it can be wrapped as warmly as desired; and it will generally be a good baby, and certainly a pretty one in its mother's eye.

Now, about the cord. What is the use of two or three inches of that, full of blood, but to furnish material for sepsis? My way of treating that is, first, put on the two ligatures and separate the funis between them; then, after the child is cleansed (using melted lard or vaseline instead of water and soap), the end of the cord is snipped off along with the ligature and the gelatine thoroughly squeezed out, after which it will rarely bleed to any amount; but, for fear it should, it is tied again as close to the abdomen as can be done without including the integuments. It is then left entirely alone—no band, no application of any kind—and in twenty-four hours the remains of the cord will be nothing but a scab, and in four or five days will drop, leaving a cicatrix in its place. The belly-band, make it of what material you will, is nothing but a relic of barbarism, and of no more use than a band around the head to prevent the fontanel from enlarging—uncomfortable and mischievous in its effects, many times causing and never preventing hernia of any kind. It is a well-known anatomical fact that the inguinal region is the weakest in the abdomen. The band does not protect that in the least; on the contrary, forces the intestines down to it. Even if the umbilical opening has not properly closed, the pressure of a band around

the circumference of the body will only keep a knuckle of intestine in the opening and very effectually prevent its closing, which it will generally do if left alone. Who would think of trying to cure an umbilical hernia with a broad band alone?

During my first fifteen years in practice, I used the ordinary band and compresses for the navel. In that time I had two fatal cases of umbilical hemorrhage after separation of the cord, and several of hernia requiring treatment. For the last twenty years, having a much larger obstetrical practice, and treating every case as indicated above, I have had no hemorrhage, no inflamed or ulcerated navel, and but one case of umbilical hernia.

Society Reports.

GERMAN MEDICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, May 14, 1888.

Vice-President Lawrence Wolff in the chair. Charles L. Weed, Secretary.

Dr. Carl Seiler read a paper on

Hypertrophy of the Tonsils.

He opened his remarks by stating that as yet we did not know whether the tonsils performed any physiological function or not, but that the view was prevalent that these organs were residuary and of no use in the economy. He stated further that in the normal condition they were invisible, and became visible only by an hypertrophy of their tissue. This view had lately been forcibly expressed by Dr. Daly, of Pittsburgh, and found a proof in the fact that, even when slightly hypertrophied in youth, they usually disappeared at the age of 25 or 30 years. They had no connection whatsoever with the genito-urinary apparatus, as had recently been asserted.

After briefly describing the minute anatomy of the tonsil, the lecturer entered upon the subject proper, and said that we could recognize three distinct varieties of hypertrophied tonsils: first, the ordinary soft hypertrophied tonsil, most commonly met with in childhood and early youth, and rarely found in adult age. This variety is characterized by simple enlargement of the the tonsillar tissue, with a corresponding increase in the size of the crypts, which latter mostly contain plugs of white cheesy secretion. This secretion, in some cases, becomes putrid and emits an extremely disagreeable odor. This simple hypertrophied tonsil is frequently the seat of periodical acute inflammation, which may or may not produce parenchymatous suppuration. Coexisting with this chronic tonsillar hypertrophy, we usually find a chronic nasopharyngeal catarrh and more or less hypertrophy of the pharyngeal tonsil. These conditions give rise to a variety of symptoms, the most prominent of which are interference with proper vocalization and articulation, insufficient aeration of the blood, gastric disturbances, and frequently catarrh of the middle ear.

The second variety is the so-called scirrhous tonsil, first mentioned by Dr. Jarvis, of New York, which is characterized by a smooth exterior surface and a hard cartilaginous feel to the touch of the finger or probe. The crypts are usually not enlarged, and, if so, rarely contain the cheesy secretion. This variety of hypertrophied tonsil is met with usually in young adults, and is rarely, if ever, the seat of acute periodical inflammation. The hardness is imparted to it by a deposit of connective tissue between the cellular elements, and particularly around the blood-vessels, canaliculizing them and thus depriving them of their contractility. They interfere, by their presence, with vocalization and articulation; and nasopharyngeal catarrh, as well as chronic laryngeal inflammation, frequently coexists with them.

The third variety may be called the ragged hypertrophied tonsil, and is nothing but the result of the first variety having been the seat of frequent tonsillar abscesses, which have caused parts of the tissue to slough away, leaving a ragged mass of tonsillar tissue between the faucial pillars. It is usually found in young strumous adults, and is perhaps the most dangerous to the general health, inasmuch as it gives lodgment to septic material, and thus, in many cases, produces chronic septicæmia.

Dr. Seiler then entered into the consideration of the treatment of hypertrophied tonsils, and said that in all cases the offending masses should be removed, but that the method by which this was to be accomplished should be carefully considered and adapted to the requirements of each individual case. All chemical caustics applied to the surface of the tonsil were worse than useless, as their application gave rise to a great deal of pain and had to be kept up for a considerable length of time to produce

any results at all. In the ordinary soft variety, the tonsil was best removed by ablation with the tonsillotome. Care should, however, be taken not to wound the edge of the anterior pillar, because a small branch of the tonsilar artery runs close to this edge, and, when cut, gives rise to hemorrhage difficult to control. If the anterior pillar is adherent to the tonsil, it should be loosened, and if this is not possible, owing to the bands of fibrous tissue connecting the pillar with the tonsil being too strong to be torn, the tonsillotome cannot be used with any degree of safety, and the galvano-cautery knife should be used. After the projecting portion of the tonsil had been ablated, the cut surface should be brushed over with a 60-grain solution of nitrate of silver, to cause contraction of the capillaries and to cover the wound; and any secondary hemorrhage, which, however, rarely occurred, should be controlled with a strong solution of tannic and gallic acid, used as a gargle. The old method of removing the tonsils with the volsellum and bistoury, the lecturer said, was unsafe, as the edge of the anterior pillar, even when not adherent, was too easily wounded by the heel of the knife. Total extirpation or enucleation was also dangerous, besides being unnecessary, except in the extremely rare cases of cancerous growth in the tonsil.

The safest and only applicable one in cases of ragged tonsil was the galvano-caustic method of removing hypertrophied tonsils. In applying this method, the galvano-cautery knife should be heated to a bright red heat and should then be pressed into the tissue of the tonsil by entering one of the crypts and cutting with it from within outward, so that the eschar resulting from the burn can easily fall off and does not become impacted in the tissue of the tonsil. This procedure, Dr. Seiler said, did not give rise to any pain, and should be repeated at intervals of a week or ten days, and from four to six applications usually sufficed to reduce the tonsils to a size compatible with health and comfort of the patient. Under no circumstances should any operation for the removal or reduction of hypertrophied tonsils be undertaken while the organ was in a state of acute inflammation. In the case of the ragged tonsil, scraping the tonsilar tissue from the capsule with a sharp curette had been recommended; but this method was not only very bloody, but also painful, and on that account the galvano-cautery was to be preferred.

For the removal of the scirrhous tonsil, Dr. Seiler recommended the Jarvis snare as the best and safest instrument. The steel wire loop should be laid around the enlarged tonsil, and, by turning the screw, should be gradually decreased in size until the portion encircled by the wire was cut off. If done slowly, the operation occasioned very little pain, and time was given for the edges of the rigid vessels to become agglutinated, so that little or no hemorrhage resulted. The best way, he said, was to start the snaring process and then let the patient turn the screw himself, trusting to him that it was not done too quickly; for the patient would tighten the loop until he felt the pain, and would then stop, to begin again when the pain had ceased. The time occupied in thus removing a scirrhous tonsil was from two to three hours.

Dr. Muehleck, in opening the discussion on Dr. Seiler's paper, suggested that many of the supposed cases of hæmophilia were cases of scirrhous tonsil, in which the canaliculization of the vessels caused profuse and persistent hemorrhage after ablation. For this reason he asked the lecturer to definitely state the diagnostic differentiation between the soft and fibrous forms.

Dr. Vansant desired the judgment of Dr. Seiler upon the use of alkalies in acute tonsilitis, especially of sodium bicarbonate and borax. He inquired, furthermore, whether, after repeated attacks of inflammation, the resulting hypertrophy ever spontaneously disappears. In the matter of diagnosis, it should be borne in mind that other tissue-changes than simple inflammation and hypertrophy may have their seat in the tonsils. It is a question whether or not the initial lesion of syphilis would be likely to lead to such error. The cases he had observed presented a mere superficial ulceration without induration. In none of the cases reported by Tchisbriakoff, Peterson, Tomashevsky, and Severi within the past year was the fact of induration mentioned. He would like to know whether this peculiarity is constant in a lesion in this location.

Dr. Wolff had had considerable success in aborting acute tonsillitis by Dr. Seiler's method—viz., by penciling with a 25 per cent. solution of silver nitrate. The attacks were, however, aborted only when the application was made within the first twenty-four hours; nevertheless, even a later application was generally successful in preventing suppuration, besides giving great comfort to the patient by reducing the tension and pain.

Dr. Friebis noted the frequent association of tonsillar hypertrophy and otitis media, but was not clear in his mind whether the

same is to be attributed to impeded nasal respiration (mouth-breathing), or to the septic influences from the crypts, or to mechanical obstruction of the mouth of the Eustachian tube by the swollen gland.

Dr. Miller, in using the cautery knife, had frequently had it stick in the tonsilar tissue, and had caused pain and hemorrhage by its violent removal. This difficulty was due to a too early shutting-off of the current, and could easily be avoided. The knife should be hot when applied and removed. He had used the galvano-cautery more often than the guillotine—even in the soft variety—owing to an unconquerable prejudice on the part of the patients against any cutting operation. For the same reason the blade must be heated after it is in the mouth, so that the patient may not see it. If both tonsils were treated at one sitting, deglutition would be rendered unnecessarily painful. He treats them, therefore, in alternation, with two sittings per week. He reduces them so that they do not project beyond the pillars, and leaves the rest to cicatricial contraction. A most useful battery for the purpose is that of Dr. Seiler. The method of gouging out the growth with the finger is not only barbarous but dangerous. He would not agree with the lecturer that the tonsils are necessarily in a pathological state when they fill the space between the anterior and posterior pillars and do not extend beyond them.

Dr. Weed quoted the two cases reported by Croly, of primary sarcoma of the tonsil, in both of which incisions were made to evacuate the supposed abscess. Such an affection might be mistaken for an hypertrophy even more easily than for quinsy, and the guillotine might evoke a dangerous hemorrhage. In cases of acute tonsilitis, the diagnosis is rendered difficult by the fact that a variety of affections have here their local manifestations. Le Gendre considers the tonsil the site of the initial lesions of scarlatina and diphtheria, and Fränkel calls attention to other varieties of septic infection from this gland. Le Brun looks upon all tonsillitis as infectious, and regulates his therapeusis accordingly; on the other hand, Frölich reports a group of cases, in some of which the tonsil seems to have been the seat of local lesion, although not the point of original inoculation. The first case was one of so-called follicular tonsillitis followed by a fatal suppurative peritonitis. At the autopsy, Frölich and his assistant sustained slight wounds with a resulting follicular tonsillitis. A number of the household developed similar symptoms. In addition to the cases of syphilitic inoculation quoted by Dr. Vansant are a number collected by Dr. Delavan in the Annual of the Universal Medical Sciences, just published. There being, therefore, so many varieties of acute tonsillar inflammation, it is idle to vaunt any one remedy as being suited to all cases. The strong solution of nitrate of silver had in the speaker's hands seemed to abort the attacks of recurrent quinsy, or had at least modified the process, but had failed in other forms of inflammation. He was unable to state whether the virtue of the silver salt was in its astringency or in its germicide power. In tonsillotomy for hypertrophy it is, according to the experiments of Zuckerkandl, impossible to wound the internal carotid without cutting the wall of the pharynx.

Dr. Seiler, in closing the discussion, said that the differentiation between the soft and scirrhous varieties of hypertrophy was easily made by the sense of touch, the former being soft and doughy while the latter was hard and cartilaginous and never occurs before the age of puberty. He believed that an initial lesion of syphilis upon the tonsil was never indurated. This was owing to a poverty of submucous connective tissue. An early diagnostic sign is glandular involvement at the angle of the jaws. The much-vaunted alkaline treatment of acute tonsillitis with bicarbonate of soda or borax had, in his experience, given no results greater than a temporary alleviation of the pain. The only abortive treatment with which he had had success was that mentioned by Dr. Wolff. There is no doubt that hypertrophy of the tonsil does sometimes disappear with the advancing age of the patient. This is due to a physiological atrophy of the glands. The periodical attacks of acute inflammation may be prevented by a proper tonic treatment, attention to hygiene, and particularly, by ablutions of the neck and chest, morning and night.

—The *New York Times* says that an infant, eleven months old, was taken ill suddenly one day last week, in Hart Park, S. I. A doctor could not determine what ailed it. Finally, Mrs. Grinnell discovered a long piece of black thread hanging down from its stomach. She endeavored to pull it out, but could not do so. A doctor was summoned, and, after cutting the skin, found a needle about two inches long attached. He pulled it out, and the child is reported to be getting well. It is thought that the needle was lying on the floor with the point raised, and that the baby crept on it.

Special Correspondence.

MEDICAL JOTTINGS FROM THE OCCIDENT.

San Francisco, Cal., May 28, 1888.

No. 2.

Since my last letter, I have visited *one* of the State Lunatic Asylums—Stockton. The second is situated at Napa, and a third is in construction at Santa Clara. Three asylums, one State of a million population. Do not adjudge us all insane! It is supposed by our genial "glorious climate" advocators that, like phthisis pulmonalis, the majority of these cases are imported from the East. The pet expression of an enthusiastic Californian, "God's own country," does not always bear a close examination. Lung-troubles of all kinds in San Francisco head the list of death-rate. The loyal "Frisconian" tells you of importation, dreadful climate of the East, &c.; but an unbiased observer can readily see, in the *t. d.* changes of climate in "Frisco," sufficient reason for lung, throat, and catarrhal affections. The well-known restriction to State Asylums of those only who are residents of the State and become insane within the State shows at least one thing—that our glorious climate does not prevent lunacy. I do not know anything of the usual per cent. of insane to population in the East or elsewhere, but that Stockton has 1600, and, although only built four or five years ago, already complains of lack of room; that Napa has perhaps as many more, and that the demands of room require a new building at Santa Clara—all go to show to me not a very favorable report.

Dr. Mays, the superintendent of the Stockton Asylum, is a man who seems to be especially fitted for his position. He is Professor of Mental Diseases in the University of California. The Doctor put me in charge of Mr. Stockwell, the supervisor, who kindly showed me carefully the entire make-up and management of the institution.

The grounds occupy 107½ acres, the male and female departments being separate affairs, at least one-fourth of a mile apart. The condition of the wards, the protection against fire, the system of prompt communication with the central office, are all that one could desire. An improvement in drainage could be made. The experiment of disposing of the sewage-matter on the land has not been wholly successful, on account of the adobe character of the soil, which had never before been cultivated. Little difficulty will be experienced during the summer season, when the ground is dry; but, when saturated thoroughly by the winter rains, the land does not absorb the offensive matter, and some plan should be adopted whereby the drainage of the asylum can be discharged into some water-channel, to be carried away by the winter's floods without becoming offensive and dangerous to the health of residents of the vicinity.

As in this climate vegetables grow the year round, about enough is raised for the demand, except potatoes. 2000 loaves of bread a day are baked, and a fine palatable article is produced. A dairy barn accomodating seventy cows of blooded stock comprises a portion of the property of the institution. Dr. Mays is quite conservative as to the use of medicines. He has found but little use for some of the newer and extolled hypnotics. Freshly prepared (always) chloral solution and the bromides are the standbyes. Moral treatment is the chief reliance, and he turns out forty per cent. of cures. The straight-jacket is abolished; straps and muffs are the only restraints used. Dr. Mays is a firm believer in the advantages of early hospital treatment of insanity. He says it is only the recent cases that recover. If the patient has been in the asylum a year and a half or two years, his prospects of restoration are fast dwindling to a vanishing point. He is sure that the fact remains that, if taken in time, in its early stages, insanity is as curable as the average run of diseases, except where there is a palpable hereditary fault. The cure-rate of those who have been insane over four years ranges *below one per cent.* A certain number of the forty per cent. dismissed cured will relapse, of course, for it is known that one attack of brain-disease predisposes toward another; but is it true, after all, says Dr. Mays, that the liability to after-attacks is any greater in affections of the brain than it is in disease of the heart, kidney, or other organ? He thinks Maudsley's estimate, that, of those discharged as cured, one-half will be returned sooner or later, over-high.

Dr. Mays has been doing good work in scattering the modern distrust of insane asylums. He delivered an address at the graduating-exercises of the Medical Department of the University of California, November 15, 1887, in which he made this subject his text. He asks how we shall account for the suspicious feeling that seems to pervade the public mind with regard to insane asylums—how account for the ready credence

given to stories of cruelty and outrage, stories either coined from the distorted brain of some half-cured patient, or else the malicious invention of some discharged employé? Why do people who in other affairs of life exercise a wise reservation of judgment join at once in the chorus of detraction? There is evidently a deep-rooted distrust on the part of the public generally. The answer to these questions is that it is a residue of a once prevalent habit of thought, of a feeling that once had good reason to exist. The traditions of centuries are not overthrown in a day. He further says: "For a thousand years the very conception of insanity was enough to strike terror to the stoutest heart; for hundreds of years a lunatic asylum was the most loathsome and dreadful of prisons—the abode of suffering and misery. These horrors were stamped, generation after generation, upon the minds of the people at large, until the memory of them has been handed down like an instinct, and this is the heritage that the modern asylum has to contend against."

PERISCOPE.

Case of Hæmatoma of the Vulva in a Non-pregnant Woman.

Himmelfarb (*Centralblatt für Gynäkologie*, No. 9, 1888) says that hæmatoma of the vulva usually occurs during pregnancy, and most frequently while birth is taking place. It has been occasionally observed as a result of direct violence. The author reports a case in which the labium was bitten immediately after coitus. The woman felt much pain, and noticed that a large swelling of the right labium majus developed quickly. She did not seek advice for a week. When examined the swelling was found to be the size of a large man's fist. It was oval in shape, and involved the whole length and thickness of the labium; it concealed completely the entrance to the vulva, and had to be drawn on one side to allow the urine to be passed. The swelling was very painful, bluish-red in color, elastic and slightly fluctuating. There were no varicose veins either of the labia or the legs. Cold compresses were applied, and after a few days' rest the pain disappeared. The swelling was then opened, the clots cleared out, and the wound plugged with iodoform gauze. The dressings were changed daily at first, and then every second or third day. The wound healed in three weeks. The case is of interest on account of the size of the swelling. All authors state that hæmatomata occurring in a non-puerperal state attain only small dimensions. Zweifel says they are never larger than a hen's egg; and Hildebrandt that they may be as large as an apple, but that, owing to the hardness and resistance of the subcutaneous and subfascial tissue, they are more sharply defined and rounder than when occurring in the puerperal state. In the case related the swelling was oval, and at least as large as a man's fist. Usually they are caused by great violence, and only a few cases have been recorded in which a slight injury has been sufficient. The only reasons which could be found for the existence of hæmatomata in three such cases the author has collected were respectively overstraining at the stool by an old woman, the lifting of heavy patients by a young nurse, and the clumsiness of a husband on the first night of his married life. Himmelfarb suggests that possibly the congestion of the parts after coitus may have had something to do with the size of the tumor.—*Medical Chronicle*, June, 1888.

Therapeutics of Hay-Fever.

Dr. Carl Genth, in a communication to the *British Med. Journal*, June 16, 1888, says that for the past ten years a young medical man of his acquaintance has suffered so severely from hay-fever from the beginning of May to the end of June that his practice has been seriously interfered with. It will be understood, as a matter of course, that he had, in succession, tried all the many and much-lauded remedies without any good result. Quinine, in large quantities, alone produced favorable results, and not before symptoms of poisoning presented themselves. It may not be without interest to mention that urticaria broke out, beginning on each side of the spine, following the course of the chief nerve-branches down the arms and legs, and finally covered the whole body. This painful state lasted for three days, at the end of which the hay-fever disappeared—leaving in the patient, however, no desire to repeat the experiment with quinine.

In a comparatively large number of cases of hay-fever, Dr. Genth has found that the primary indication of the disease is a slight twitching sensation at the inner corner of the eye. This sensation becomes more intense day by day; next follows a swelling of the conjunctiva, with all the accompanying symptoms of acute conjunctivitis. The symptoms referable to the mucous mem-

brane of the nose—asthma, etc.—set in later. These slight premonitory symptoms, which sometimes precede the final outbreak by a fortnight, and perhaps disappear with a change of weather, may easily be forgotten. But even assuming that, now and again, the disease does not begin in the eyes, but in the nose or the bronchial tubes—a possibility which, in principle, cannot be rejected—the exception would not by any means invalidate the assertion that hay-fever usually begins with the symptoms of conjunctivitis.

Upon these facts he builds his therapeutic plan. Since the first symptoms of hay-fever manifest themselves in the eye, it is probable, he says, that the agent which is to be regarded as the cause of the hay-fever (he does not here refer to the pollen grains which are everywhere present during the season in which the fever prevails, and are consequently to be found in the secretion of the conjunctiva and in the mucus of the respiratory tracts) first attacks the conjunctiva. Under favorable circumstances — such as heat—it multiplies there, and then diffuses itself over the mucous membrane of the respiratory organs, perhaps through the medium of the lachrymal canal. To be effective the condition must be attacked by local treatment, directed to the eyes at the earliest possible date.

On the advice of Dr. Pagenstecher, of Wiesbaden, Dr. Genth chose instillation and bathing of the conjunctiva with sublimate solution of the strength of one in 3,000. The bathing began, perhaps, fourteen days before the appearance of the hay-fever, whenever the patient returned home after open-air exercise. The patient was, besides, required to keep as cool as possible, and to wear pale-blue spectacles. The result of the treatment was that he remained free from his trouble for a length of time. Not before the end of June did slight irritation of the conjunctiva reappear, which, however, could not be compared in intensity with former attacks, and involved no complication. Relying, probably, upon his generally healthy condition, the bathing had not been performed with sufficient energy. Although the sublimate solution came in contact with the mucous membranes of the nose or throat only slightly, or perhaps not at all, neither of these organs was affected, which would have happened if the virus of the hay-fever passed into the body through the nose and mouth. In such an exceptional case, he says, it would be simple enough to apply the solution by a nose-douche, by gargles, or perhaps even by cautious inhalation.

Functions of the Sinuses of Valsalva and Auricular Appendices.

Mayo Collier (*Lancet*, June 16, 1888) summarizes his opinions formed from a study of the functions of the sinuses of Valsalva and auricular appendices, in the following words: 1. The sinuses of Valsalva are constant features of all mammalian and avian hearts. They are not pathological formations, but, on the contrary, are absolutely essential to the efficient action of the semilunar valves. 2. The musculi papillares serve the same purpose for the auriculo-ventricular valves as do the sinuses of Valsalva for the aortic. 3. The auricular appendices probably complete the distension of the ventricles without appreciably altering the general tension of the auricles. 4. The first sound of the heart is not due to the sudden tension of the tricuspid and mitral valves. 5. The semilunar valves open and shut gradually; the second sound of the heart being due to the sudden difference of pressure on the two sides of the valves at the moment of commencing diastole of the ventricles, causing them to vibrate. 6. At each systole the contents of the ventricle distend only a segment of the length of the aorta, the force of the ventricle exerting little influence directly on the general circulation, but indirectly by the recoil of the elastic aorta. 7. That the pulse is due to a wave of dilatation and recoil, which wave is normally single. 8. That when the arterial tension is below a certain standard, one or more secondary pulse-waves can frequently be felt, due to a redistension of the penultimate section and its consequent repeated recoil.

Use of Saccharine to Prevent Ammoniacal Change in Urine.

Dr. James Little, President of the King and Queen's College of Physicians in Ireland, in a paper read before the Section of Medicine of the Royal Academy of Medicine in Ireland, April 20, 1888, says that the management of cases of chronic cystitis has been greatly improved of late years, and as a consequence its power of inducing secondary changes in the kidneys, and so destroying life, has been greatly lessened. Of these improvements, he thinks the first place is due to the manufacture of catheters which can be easily used by the patient himself without risk, by which means the accumulation of residual urine in the bladder is prevented. At the same time, medical men have become impressed with the neces-

sity of urging scrupulous cleanliness in the instruments introduced into the bladder—a precaution which, a few years ago, was certainly neglected. As a consequence of the introduction of catheters which can be passed without pain or violence, he believes much relief has been given, and ammoniacal changes in the urine prevented by washing out the bladder with warm water or antiseptic solutions; but, he says, it has always appeared to him that it is better, if it is possible, to keep the urine free from decomposition by medicines given by the mouth, and so reduce instrumental interference to a minimum. This practice he has always followed, especially in the case of aged persons who have come into his hands, and in whom chronic cystitis constituted part of their sufferings. Unfortunately, such patients have not infrequently irritable stomachs, as well as irritable bladders; and most of the drugs which are useful in keeping the urine sweet are liable to disagree and cause sickness. This certainly applies, he says, to the remedies which were chiefly used a few years ago—quinine, tincture of perchloride of iron, benzoic acid, and benzoate of sodium. Boric acid, which has been more used of late, is not so likely to sicken, and is, he thinks, best given in lemonade.

For the past three years, he says, he has been asked, from time to time, to see a woman, nearly eighty years of age, who is quite confined to bed in consequence of chronic disease of the bladder, which gives rise to frequent and painful calls to pass water. The urine always threw down a copious purulent sediment, and, except when decomposition was prevented by treatment, was always ammoniacal. The patient has many times passed, with great suffering, phosphatic calculi, and Dr. Little thinks many such exist in the bladder, but she has always refused to permit any surgical interference beyond the occasional introduction of a soft catheter and the washing out of the bladder by a woman who acts as her nurse. Quinine and boric acid, when taken in fair doses, always purified the urine; but about three months ago her stomach became so irritable that these drugs could not be borne, and the washing out of the bladder with a weak warm sublimate solution could no longer be practiced, as the passage of the catheter had become exquisitely painful. The consequence was, that the urine became so offensive that the odor met one on the stairs, and the patient's attendants had often to leave the room to avoid being sick. In this difficulty it occurred to Dr. Little to try saccharine. He directed six of the tabloids to be used daily. In three or four days the urine was no longer offensive. The patient has continued their use ever since, and the urine has not again become ammoniacal, though there is little, if any, diminution in the quantity of contained pus.

Since the foregoing case came under his observation, he has had four other opportunities of observing the effect of saccharine in patients who were passing ammoniacal urine. They were all males: one a case of catarrh of the bladder, in a paraplegic gentleman; one a case of chronic cystitis, with enlarged prostate; and two cases, in which there had existed stricture of the urethra, but in which, although a surgeon had successfully dilated the stricture, the urine remained ammoniacal. In all these cases the saccharine was distinctly useful, but in all its administration had been combined with the daily use, by the patient himself, of a catheter, so as to prevent the accumulation of residual urine in the bladder—a precaution without which no drug will prevent decomposition of the urine.—*Dublin Journal of Med. Science*, June, 1888.

Damson-Stone Lodged in the Right Bronchus; Tracheotomy; Recovery.

The following case, under the care of Mr. Reginald Harrison, is reported from the Liverpool Royal Infirmary: Jane S., 8 years old, was admitted on April 4, 1888. Ten days previously, while laughing when eating some damson jam, she thought she had swallowed a stone. This was immediately followed by a violent fit of coughing, for which medical aid was summoned. These paroxysms of coughing were repeated at intervals. On admission, there was slight flattening of the right side of the chest posteriorly, with diminished expansion; and a rhonchus was distinctly audible. Breath-sounds feeble toward base, the rhonchus increasing in loudness as the bronchus was approached opposite the fourth dorsal vertebra, where the sound was best heard. The rhonchus was twofold, inspiratory and expiratory; and there was sometimes a sound as if something fell between expiration and inspiration. Breath-sounds on the left side normal, but with transmitted rhonchus; respirations 22; pulse 80. Whilst she was under observation in the infirmary she had several attacks of violent paroxysmal cough, when various expedients, including inversion and slapping on the back, were tried, with

the view of favoring the expulsion of the damson-stone, which evidently had found a resting-place in the right bronchus. On one occasion she expectorated a little blood, but as a rule she was going about the ward apparently well.

On April 21, she was placed under chloroform, and Mr. Harrison performed tracheotomy. An incision having been made as low down as possible through the skin, the trachea was quickly bared with a blunt director. A free incision into the trachea was then made, three or four rings being divided. Just as the child was being inverted, the stone was shot out into the wound, where it was easily seized with the fingers. A tracheotomy tube was introduced and retained for a few hours, but proved useless. The patient breathed freely through the opening, and expectorated for the first four or five days a considerable amount of pneumonic-looking sputum. Then convalescence rapidly took place, and she left the infirmary quite well fourteen days after the operation, with the wound completely healed.—*British Med. Journal*, June 23, 1888.

Peculiar Neurosis Allied to Chorea.

Dr. W. T. Gairdner, in reporting this case to the Medico-Chirurgical Society of Glasgow, April 6, 1888, said: "G. C., thirty-three years old, assistant timekeeper. This man is the subject of a kind of clonic spasm, or 'insanity of the muscles,' resembling chorea as regards the individual irregular movements, in that they are altogether non-rhythmic, and, as it were, out of all reckoning as to order and sequence; but, on the other hand, so far from affecting, as chorea commonly does, those actions most which are normally the *most* volitional and the most highly differentiated, it is in fact the opposite class that is here usually the most involved in the disease. Thus, he can carry a full glass to his mouth with either hand, and without any notable disturbance; he can walk perfectly well, can write in a good ordinary hand, which shows almost no traces even of tremor. When he is at rest in the recumbent posture, there are times when it might appear as if nothing were wrong; but if he is caused even to speak, or to make any kind of movement when in the position of dorsal decubitus, spasms come on, more or less, *but not necessarily*, or even chiefly, in those muscular groups which are thus called into voluntary action.

"I have witnessed the spasms to-day in many parts of the trunk of the body and neck—*e.g.*, the rectus abdominis, especially the left and the upper part; the platysma, and probably some of the deeper muscles in the same situation; the muscles which act upon the larynx and trachea *from without*, but *not at all* the internal muscles of the larynx; the facial muscles, grimacing spasm in a mild degree; the muscles of respiration, *only* to the degree of giving rise to slight irregularities, often attended by involuntary emission of sounds, but *not* any asthmatic or other serious embarrassment; the muscles of speech, to the extent of *only* just perceptibly affecting his articulation, but never of making him at all unintelligible. The vesical and alvine evacuations are normal; so are mastication and deglutition, so far as I have been able to discover. The knee-jerk may be taken as normal. The other reflexes have not been investigated. The disease appears to be wholly unaccompanied with pain or fever; but the patient has noticed flushing of the face at times. This used to be more frequent than it is now. The general health is good, and has always been so.

"These symptomatic details appear to me to bring the disease into a certain relation with chorea, but not with any of the tremors, properly so called, nor with paralysis agitans, or disseminated sclerosis in particular.

"The disease has persisted, more or less, for ten or twelve years; it was first observed in the facial muscles, and does not appear to have been of very sudden origin. It was recognized by Dr. Lorraine, of Castle-Douglas, at this time as 'resembling St. Vitus's Dance.' No cause can be assigned, unless it were his having got a knock on the top of his head from jumping up in an entry. He has never had venereal disease. The remedies he has had hitherto have been chiefly these, so far as he knows: 1. Arsenic (Fowler's solution) from Dr. Lorraine, in full doses, and for a long time. 2. Nux vomica, also for a long time. 3. Easton's syrup. 4. Fellows's syrup (one bottle). 5. Belladonna—which did not agree. 6. Indian hemp. 7. Phosphide of zinc. 8. Sulphate of zinc and extract of conium, together, which he thinks has checked the spasms more than the other remedies, and he has accordingly taken it in large quantities. 9. Continuous current, which he thinks did no good. 10. Blisters on back of neck, and iodine painting. 11. Cold water compresses to spine."—*Glasgow Med. Journal*, June, 1888.

Optic Atrophy in Three Brothers (Smokers).

At the meeting of the Ophthalmological Society of the United Kingdom, June 14, 1888, Mr. Edgar Browne (Liverpool) read a paper on this subject. In the first patient, forty years old, vision had failed at the age of twenty-seven. A diagnosis of tobacco-amblyopia was made. The patient reduced smoking gradually, but continued to chew. Vision had steadily failed to shadows, but the pupils were three millimetres in diameter, acted to light, and the patellar reflexes were good. Previously, vision was good; general health always good. Optic discs: typical skim-milk atrophy, with attenuated vessels. He could see a flame or bright reflection from white at the periphery of the fields. The second patient was thirty-three years old; sight became very bad six months before; he also both smoked and chewed tobacco; he could see a little in twilight. The knee-jerks were good. Pupils, three millimetres in diameter, acted to light. The optic discs showed a general appearance of atrophy; vessels pervious, but rather small. He could see white paper test in lower temporal (right) and lower nasal (left) fields, but not at all centrally. In the third patient, vision had failed for two years, patient being twenty-three years old; could read J. 16. This patient discontinued smoking when warned. Pupils sluggish, but acted to light. Peripheral fields for white: both eyes normal; central scotoma for white and red in left eye, for red only in right; color-vision with wools good. Optic discs very white and smooth; veins perhaps a little large. The original assumption that tobacco could cause atrophy had been rather discredited since the significance of axial neuritis had been understood. These cases, he said, were closely related to the hereditary optic atrophy of Leber (though occurring rather late), but the term hereditary should not be adopted till our information was much more exact. In all three cases, tobacco was probably the determining cause of the atrophy. In all, perception of light was better toward periphery than centre; none had visible neuritis; none had cerebral or spinal symptoms. The father, mother, and two sisters had good sight; a collateral relation had suffered. These cases might be taken, he said, as types of one group—namely, those in which an axial neuritis being once established tended to spread to the peripheral fibres, involving both sets in the subsequent atrophy. Exactly the opposite occurred in ordinary neuritis, in which the central fibres (and vision) might escape for a time. The following grouping of cases was suggested: 1. Ordinary tobacco-amblyopia, involving only central fibres; transient, and recovery occurs on removal of the cause. 2. A class beginning with central negative scotomata, which progressed downward till central defect became positive (or nearly so), and axial atrophy might be assumed, peripheral vision being unaffected. The part played by tobacco in these cases required investigation. 3. Cases like those under consideration, in which retro-bulbar neuritis, beginning centrally, spread peripherally, giving rise to more or less pronounced atrophy. Here, he said, the personal proclivity was shown in young persons, members of the same family. If similar groups were found among non-smokers, search would not be required to discover the exciting agent. Beyond these were (4) consecutive atrophy, and (5) atrophy accompanying spinal degeneration. At present the two last groups were well understood, but cases illustrating the second and third groups should be collected. Mr. Hutchinson mentioned a group of three, consisting of two young males who smoked, and the mother of one of them (and aunt of the other) who did not smoke, all affected with optic nerve atrophy. In the case of the woman, the inherited predisposition to nerve lesion must have been very strong. Eventually she became quite blind, but had very good health. Perhaps abuse of tea or coffee might have had a share in bringing about this effect; he was sure that they sometimes caused deafness. He thought the society might investigate the very rare group of women affected with this form of atrophy who did not smoke at all. Mr. Browne had mentioned that his first patient was a total abstainer; this, Mr. Hutchinson thought, rather led to the production of the atrophy than the reverse. Those who indulged in alcohol as well as tobacco were less liable to tobacco atrophy than were abstainers. These cases occurring in families were much more severe, more liable to end in blindness, and much less easily cured than the other forms. Dr. Emrys-Jones mentioned the case of a family of nine children, but only five living, in which two children had atrophy of the optic disc without definite cause, the girl at the age of seventeen and the boy aged nine; total blindness ensued.—*British Med. Journal*, June 23, 1888

—Dr. Y. D. Harrington, of Terrell, Texas, died June 11, 1888.

MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

LAPAROTOMY FOR TUBERCULAR PERITONITIS.

A large number of cases are now on record, in which the abdomen has been opened to determine the nature of some obscure disorder, with the result of discovering extensive tubercular deposits in the peritoneum. In these cases, the surgeon has usually carried out a thorough cleansing of the abdominal cavity with some disinfectant solution, adding at times an application of powdered iodoform to the affected surfaces, and afterward closing the wound—the whole procedure being called an exploratory laparotomy. When this was first done, it was with a sense of disappointment, and the operation was regarded at best as one which did not often imperil the life of the patient. But after a while it was noticed that patients so treated often improved manifestly after the operation, and men began to associate the idea of this improvement with those ideas of the nature of tuberculosis of the peritoneum which König has, since 1884, done so much to impress upon the mind of other surgeons. According to these ideas, tuberculosis of the peritoneum is not a mere manifestation of a general disease, but a local affection, and amenable to local treatment, just like tuberculosis of the bones and joints.

As might have been expected, the fortunate issue of operations which may be regarded as accidental *quoad hoc* led to the proposition that the abdomen should be opened and the peritoneum subjected to direct treatment, as a formal method, when there was good reason to believe or to suspect that it was affected with tuberculosis. Not only has this proposition been made, but it has been also carried out in a considerable number of cases. The results have been eminently satisfactory. A year ago, Kümmel reported to the sixteenth Congress of German Surgeons the history of forty cases of laparotomy in tubercular peritonitis. In only two cases did death soon follow the operation; in three of them the patients lived from five to twelve months and then died of general tuberculosis; in two a coincident tuberculosis of the lungs progressed, but no new symptoms of peritonitis appeared. In the rest of the cases the improvement was so great as to lead to Kümmel's calling it a cure. In fact, he is so convinced of the value of laparotomy that he speaks of these operations as having led to improvement in every case, and to recovery in the majority of them, and pronounces the unqualified opinion that tubercular peritonitis is a disease which may be not only relieved, but also absolutely cured. For this purpose he strongly recommends an exploratory laparotomy combined with thorough washing-out of the abdominal cavity, as an operation which promises results which render the risks inconsiderable.

The opinions of Kümmel are shared by a

number of able surgeons in Germany and in America, and deserve very thoughtful consideration. We do not feel that the statistics upon which they partly rest are absolutely demonstrative; but we have no doubt that experience justifies the operation of laparotomy for tubercular peritonitis, and especially when the peritonitis is of an active and threatening character. It seems clear that the operation, in skillful hands, is not one of great risk to life, and that its results are generally beneficial, at least for a while. This is enough to give it good standing among the operations of surgery, and the possibility that it may sometimes be followed by recovery makes its position impregnable.

THE MORRIS PLAINS ASYLUM.

Sometime ago, charges were made that the Morris Plains Asylum for the Insane, in New Jersey, was grossly mismanaged. It was asserted that food and medicine of bad quality were furnished to the inmates, and that the internal government of the institution was improperly conducted. The most prominent accuser was Dr. McFarlane. His accusations had an appearance of veracity, and were no great surprise to persons familiar with other institutions managed by politicians. But they have been denied, and are even now being made the subject of investigation by a committee of the New Jersey Legislature. It happened, on July 9, that Dr. McFarlane and Mr. Halsey, President of the Board of Managers, were on the same train, proceeding to the meeting of the committee, and it is painful to learn that Mr. Halsey "denounced Dr. McFarlane to his face as a lying scoundrel," and not surprising to be informed that thereupon Dr. McFarlane "appeared much disconcerted."

Those who share Mr. Halsey's opinion will be strengthened in their faith by the testimony of various people who supplied goods to the asylum, that their wares were always of the best quality and of full weight, and that they had great confidence in the integrity of the purchasing officer of the asylum.

On the other hand, those who sympathize with Dr. McFarlane may not at once abandon him to his fate because he has been assailed with abusive epithets by a man whom he has made to feel very uncomfortable, or discredit the charges of maladministration against the Morris Plains Asylum because a number of witnesses, implicated in these very charges, intimated their disapproval of him and their entire satisfaction with themselves.

The fact is, the case seems to be conducted too much in the fashion usual for "investigating committees," and there is some reason to fear that it may come to the customary conclusion. But the matter is so important that it is to be hoped it will be thoroughly sifted. If the Morris Plains Asylum has been properly managed, it will be well to have the fact clearly demonstrated; for there have been many who thought this was not the case. On the other hand, if the managers have been unwise or corrupt, the interest of humanity and the credit of a great State are involved in ascertaining the fact and correcting or punishing what has been wrong. The treatment of the insane is one of the most serious responsibilities of those who enjoy their reason and civil rights. Happily, this responsibility is more fully appreciated and better met nowadays than ever in the history of the world; and even such painful episodes as the one going on at Morris Plains have their uses, and indicate the wrongs which still exist far less than they show the wrongs which have been abolished, and the kind and humane sentiment which in this age watches over the rights of the unfortunate class of the insane. The eyes of all managers of hospitals for the insane are turned to what is going on at Morris Plains, and the issue cannot, we believe, fail to be helpful to them in the conduct of those institutions with which they are connected.

A FRENCH CRITIC ON AN ENGLISH WRITER.

In a review of a book on "The Passage of Air and Fæces from the Urethra," by Mr. Harrison Cripps, of London, M. A. Broca, writing for the *Gazette Hebdomadaire*, June 29, 1888, takes the author to task for speaking with the air of an authority upon the subject from knowledge derived exclusively from works published in the English language. Mr. Cripps, as is well known, has made some important contributions to our knowledge in regard to diseases and malformations of the rectum and anus, and is in many respects an author of distinction. But in his last book he has laid himself fairly open to the criticism referred to. And, the matter is a little worse than his reviewer makes it; for the studies which M. Broca says Mr. Cripps has overlooked, and which convict him of error, have already been communicated to English readers—in this country, at least.

The matter in question is of less consequence than the principle involved in M. Broca's criticism—namely, that it is dangerous to speak dogmatically on scientific subjects with insufficient preparation. Aside from the error in regard to a question of pathology pointed out by M. Broca, it appears that Mr. Cripps has made the mistake of attributing the revival of suprapubic lithotomy to the work of Sir Henry Thompson. M. Broca says — what is perfectly true—that Sir Henry Thompson is but a recent convert to suprapubic lithotomy; and he does not say—what is equally true—that Sir Henry got the courage to practice suprapubic lithotomy, and learned the way to do it, from Guyon, of Paris. The conversion of Sir Henry Thompson to the practice of suprapubic lithotomy undoubtedly did more to convert the whole body of English surgeons than all that had happened for nearly fifteen years in America and on the continent of Europe; but this is not a fact especially creditable to their independence of authority or their acquaintance with what is going on outside of Great Britain.

There is a moral in all this, to be drawn by other writers and workers than those of England. The field of medical science is too large to be viewed exclusively from the standpoint of any one nationality, and those who wish to speak with authority on any subject in it should be careful that they do not overlook those who have made important contributions to it in other lands. If they make this mistake, they are sure to do injustice to those who have preceded them, and run the risk of falling into mortifying errors themselves.

AN EXPLANATION.

A few weeks ago we received a letter from a medical man in New Jersey who was displeased with a statement made by our correspondent in Cincinnati during the last meeting of the American Medical Association, and published in the REPORTER, May 12, 1888. The statement was, in effect, that the representative of New Jersey in the Nominating Committee did not vote or act in accordance with the instructions of his delegation in a certain matter. The letter referred to contained no denial of the allegation of our correspondent, and no justification of the conduct attributed to the writer; beside this, it was so unfortunately composed that—especially as there was no intimation that it was intended for publication—it seemed an act of kindness simply to acknowledge its receipt and file it away.

It is hard, however, to know what people want. In about a week more, a medical journal of this city published a copy of this very letter, with a sensational heading, and accompanied it with an editorial which showed an utter failure to appreciate the consideration we had shown for its author.

This is one of those things which sometimes provoke an editor; but we will not return railing for railing; our contemporary will, we trust, see that its criticism of the

REPORTER was due to a misapprehension, and be sorry for it.

We owe it to our Cincinnati correspondent, however, to say that he, as a news-gatherer, reported simply that a person, whom he indicated in such a way that only those whose business it was could know who was meant, had disobeyed the instructions of those whom he represented. The proper way to meet a charge of this sort is either to disprove it or to show that what had the appearance of wrong was, in fact, right. For either of these purposes the columns of the REPORTER are open to the person concerned. If our correspondent was misinformed, we will not hesitate to publish the fact; if his information was correct, but the circumstances justified the conduct of the delegate from New Jersey, we will let him show this in the REPORTER. But we cannot admit to our columns mere recriminations, or protestations as to the quantity of honor residing in small parts of any man's body. Finally, we would not have given so much space to this matter were it not that it concerns the American Medical Association and the profession in New Jersey quite as much as it does an individual to whom we by no means wish to do any injustice.

CORRESPONDENCE.

Anecdotes of Dr. Tuttle.

Dr. Socrates Tuttle, who settled in the town of Barnet, Vt., in the first part of the present century, and died there several years since, was full of fun and very fond of practical jokes. The following are told of him:

One day he met one of his neighbors who was always fishing and hunting without success, and withal very lazy; and he addressed him thus: "You seem to be a great hunter and a good marksman; now I have a patient who is very sick and is sure to die unless I can get an owl's gizzard to feed him; if you will get me one I will give you nine shillings for it." The hunter's knowledge in comparative anatomy was about equal to his success in hunting, so he started off early the next morning in pursuit of an owl, and although there was a pouring rain all day, he traversed the forests, impressed with the desire to save the life of the doctor's patient if possible. Just at dusk when it was so dark that he could scarcely see to take aim he discovered a small owl perched upon the limb of a tree, which he shot and carried home. The next day the doctor inquired if he had got that gizzard for his patient. The hunter replied: "I was out in the rain all day yesterday and just at dark shot an owl; I cut it open but *it hadn't a sign of a gizzard.*"

The doctor had two acquaintances in his beat, who had become impressed with the belief that when Roger's men were returning from Canada, being in a starving condition, they buried considerable gold and silver coin on the island near the mouth of the Passumpsic River. They talked with the doctor about securing this prize. He advised them to go in the night when nobody would be around to disturb them, and make but little noise while they were digging. He told them that, when they got within a few inches of the treasure, ghosts would make their appearance and try to frighten them away, but that they must pay but little attention to them unless they came too near when one of the party must read a passage from the Bible which would surely disperse all evil spirits. The doctor told them to go that night, and rolled up an old Latin lexicon, in place of a Bible, which they took along with them without opening it. About dark they started off in a small boat, and commenced to dig soon after reaching the island. The doctor arranged with three of his old chums to take a boat and land on the opposite side of the island, and walk over noiselessly where the diggers were at work dressed in sheets. The three ghosts got within a few feet of the money-diggers before being discovered, in the dim glimmer of their tin lantern. They were very much frightened and one of them unfolded the Bible and hunted for a passage but could find nothing that he could read, at the same time the ghosts were slowly approaching the spot, and in desperation improvised the following passage which he thought would be effectual: "In the name of this good book I command thee to depart." The ghosts approached a little nearer. The passage was repeated, but the ghosts continued to approach, slowly, without any change in their countenances. The passage was repeated the third time, and the ghosts still, slowly, continued to approach. By this time the money-diggers were so frightened that they threw their tools and lexicon

into the river, jumped into their boat, and paddled for the shore. The doctor's old lexicon came to pieces and some of the leaves were picked up on the shores of the Connecticut River as far south as Springfield, Mass. The money-diggers never heard the last of that expedition, and Dr. Tuttle never ceased telling the story as long as he lived.

JOHN M. CURRIER.

Newport, Vt.,
July 1, 1888.

Tait Versus Battey.

TO THE EDITOR.

Sir: I have just received a marked copy of THE MEDICAL AND SURGICAL REPORTER of June 2 which contains a paragraph headed Battey versus Tait, and I trust that in fairness you will allow me to state briefly the other side of the case.

Dr. Battey's attack is much to be regretted chiefly for the reason that if he were to spend half as much energy in fighting those who oppose the progress of abdominal surgery as he does in abusing those who are concerned for it, he would do more good in the world.

In the *Atlanta Medical Journal* for January, 1887, an attack on me by Dr. Battey, more or less similar to the present, appeared and was replied to by me. That reply contained a full statement of the facts, and those facts Dr. Battey entirely ignores.

Let me briefly re-state them, not as a reply to Dr Battey, but as a method of clearing out some of the difficulties of this complicated question.

Dr. Battey says that he has sat too modestly in his chair and allowed me to talk about "my (Tait's) operation."

The absolute opposite of this is the fact. Whilst Dr. Battey has been shouting aloud for years that removal of normal ovaries should be called "Battey's operation," I have constantly urged that nothing should be called "Tait's operation." Let me call to witness numerous discussions on this side of the Atlantic, and the well-known discussions with Dr. Thalbow and Dr. Coe on your own side. Calling operations by people's names is a lazy habit, sure to breed confusion, and it has done so to a fearful extent in the present instance.

Operations should be named either on account of a leading principle involved or on account of some special, prominent, and distinctive detail. The removal of ovaries "with the theory that the cure would depend upon bringing about change of life by the removal of the ovaries" was a proceeding which seemed to Dr. Marion Sims to have an intelligent and leading principle. But Dr Sims was burdened with the notion, now abolished, that ovulation was the cause of menstruation, and therefore his wonderful enthusiasm overcame his feebler judgment, and he rushed the proceeding into popularity as "Battey's operation." Without Dr. Sims's pamphlet the theory never would have been heard of, and it is a thousand pities he ever wrote about it. His charming inconsistency alone proves this, for we find him saying that "the experience of all ovariotomists proves conclusively that the removal of one ovary will not do this" (bring about the change of life), and yet we find Dr. Battey ignoring his theory at the very outset, and removing but one ovary in the second case in which he operated; and he did the same thing in his fourth and fifth cases. We see here, therefore, that Battey had really no principle at all to go upon in his experiments, and that Sims was wholly inconsistent in his conceptions of them.

The result of it was that all over the world "Battey's operation" was recognized as what he himself called it, "normal ovariotomy," and "normal ovaries" were whipped out in this country, I know, and I think also in America, by the bushel, heedlessly and only because Marion Sims had praised "Battey's operation." In your columns Dr. Battey repeats all this by saying that he "operates for the change of life." I say again that I have operated on this principle only six times, that all my cases made easy recoveries, but that the ultimate results have proved so unsatisfactory that I entirely condemn "Battey's operation."

I confine my operations to cases where there is actual, physical, and tangible disease in the uterine appendages, and I object to any operation being named after me, because that style of nomenclature involves neither leading principle nor essential detail.

Dr. Battey says that I said nothing about this till 1879. This is not true, as my first publication on the principle was in 1873. My first case was operated upon on February 11, 1872. Dr. Battey says Mr. Tait found it necessary to resurrect a patient at the Congress in 1881 who was recorded dead years before "in his own handwriting" This is not true at all The death was not recorded by me at all, but the records of two patients were confused, and not the patient resurrected, but the proper detail of the

operation correctly supplied. All this was explained and proved to Dr. Battey before witnesses and by the patient herself, in August, 1881, in my own house, and if Dr. Battey had any skepticism on the subject it was then and there he ought to have displayed it, and not in your columns seven years later. Dr. Battey prays that he may be prevented falling into my ways, but the style and direction of the prayer reminds me of the incident when two men went up into the temple to pray, and the one who prayed was a Pharisee.

Yours, etc., LAWSON TAIT.

Chlorate of Potash Poisoning.

TO THE EDITOR.

Sir: Please let me know through the REPORTER what is to be done in chlorate of potash poisoning, if an over-dose has been given, and oblige

Yours truly, SUBSCRIBER.

July 11, 1888.

[As most of the reported cases of chlorate of potash poisoning give evidence of acute gastro-enteritis with nephritis, a rational treatment would be that appropriate for poisoning with any irritant — demulcent drinks and the like—combined with measures suitable for the congestion or inflammation of the kidneys—dry cupping over the loins, etc. If collapse is threatening, alcoholic and diffusible stimulants are, of course, to be employed.

There is no antidote and no specific treatment. EDITOR OF THE REPORTER.]

NOTES AND COMMENTS.

Purpura Rheumatica.

Dr. Wm. Osler says in the *Canada Med. and Surg. Journal*, June, 1888: "There are certain disputed points in the clinical history of purpura rheumatica (the peliosis rheumatica of Schönlein) which are illustrated by the following case: A. B., thirty years old, seen with Dr. J. H. Musser. He had been a tolerably healthy man. In March, he had a severe sore throat, which kept him at home for a couple of weeks. He returned to work, but in ten or twelve days the sore throat again came on, with fever and swelling of the left ankle. I saw him on the fourteenth day of the illness. The symptoms had been fever of moderate grade; arthritis, chiefly of right ankle, but other joints were also sore and stiff; an extensive purpuric and urticarial eruption, beginning on lip and eyelid and extending to limbs, chiefly on extensor surfaces; great swelling and finally sloughing of uvula; profuse sweats, and endo-pericarditis. At the time of my visit, the purpura was fading, but the rash was still most extensive on the legs, and was both petechial and presented the characters of purpura urticans. A considerable portion of the uvula had sloughed away, and the fauces had a deep bluish-red color. The heart-beat was outside the nipple-line; there was pericardial friction, and a systolic murmur could be heard at the apex.

"The question arose whether we had not a case of malignant endocarditis, with the extensive cutaneous infarcts so common in this disease; but the large size of the hemorrhagic spots, their swollen condition, and the fact that some of them began like 'hives,' pointed to a purpura urticans associated with articular and cardiac disease in a case of rheumatism. The joint-affection, profuse sweats, and endo-pericarditis indicate the true rheumatic nature of cases of this kind. The sore throat, so marked a feature, existed also in a remarkable case of peliosis rheumatica which I saw with Dr. Molson in 1880, and which is recorded in Vol. IX of this journal. The patient had three attacks of tonsilitis within five weeks. Sloughing of the uvula, such as occurred in Dr. Musser's patient, is occasionally met with in acute rheumatism: I recorded an instance in Vol. VII of the journal. And lastly, the existence of endo-pericarditis is worthy of note, as certain authors have laid stress on the fact that it does not occur in rheumatic purpura."

Poisonous Canned Food.

Dr. Geo. Hay, in a communication to the *Pittsburgh Med. Review*, June, 1888, says that on several occasions, during the past four or five years, he has observed that, after eating about four ounces of canned lobster or canned salmon, he has been attacked with very marked symptoms of acute saturnine poisoning. He therefore resolved to investigate, and in doing so noticed that, on the inside, the cans were generally much eroded. On the outside, they are covered with a label and also with a yellow varnish, whose main purpose, he says, seems to be to conceal the natural color of the so-called tin plate. Having removed the varnish by an appropriate solvent, he carefully scraped a quantity of the metal from the surface of the tin plate, at the same time cautiously avoiding contact of the steel scraper with the solder. Two samples obtained in this manner, one

from a lobster-can and the other from a salmon-can, were carefully analyzed. The following is the mean of the two closely agreeing analyses expressed in percentages:

Tin	13.76
Lead	61.92
Iron (with traces of other metals)	24.32

The greater portion of this iron, he says, was doubtless taken up from the iron plate upon which the more fusible alloy was superimposed. A small portion of the iron was probably an impurity in the original alloy. Looking at the above figures, it will be seen that the original alloy consisted of about one-fifth tin and four-fifths lead. Commercial block tin ought to contain about 99 per cent. tin, and is the material with which the tin plates ought to be coated. To put food, which is intended to be eaten, in wrappers of lead, he declares to be simply villainous, and urges that the scoundrels who do so ought to be punished. Chemistry, in his opinion, is rapidly becoming a low art, prostituted to the still lower art of money-grabbing.

Quarantine at San Francisco.

The *Pacific Medical and Surgical Journal*, June, 1888, says: "San Francisco claims a population of more than 300,000, and boasts of being the leading city of the Pacific Coast of America. Its quarantine establishment consists of a steam tug-boat and one medical officer, now temporarily supplemented by an assistant, for whose compensation there is no legal provision. No apparatus for disinfection nor accommodation for people under detention has been provided, for the law-making powers have furnished no means. In their absence, the steamship companies employ hired vessels anchored in the bay, where these persons, sometimes numbering hundreds, are maintained at heavy expense, estimated at about $150,000 for the months of February, March, and April. This is a single step in advance of the Turkish method of detaining ship, crew, passengers, and cargo, for an arbitrary period. Fumigation has been practiced here, in a primitive fashion, but the principal element is specific detention for the maximum period of incubation, and the rule has been extended to white passengers and pock-marked Chinese, in common with the rest; justification being found in the discovery of two well-marked secondary cases of small-pox among the coolies. Vaccination has not been practiced at quarantine during the present season, until within the last month; and indeed this would be a poor reliance with such results as have lately been obtained at the Health Office among the inhabitants of the city."

Poisoning with Gelsemium.

A case of poisoning with a preparation of gelsemium sempervirens took place recently, in Toronto, Canada. A prescription containing quinine and fluid extract of gelsemium was dispensed for a woman suffering with neuralgia, the directions being that a teaspoonful of the medicine should be taken three times a day. The remedy did not prove effectual, and the patient took it upon herself to administer six teaspoonfuls at once, with the effect of producing symptoms of acute poisoning. Medical aid was summoned, and, by liberal treatment with tincture of nux vomica, a fatal result was averted. —*Canadian Phar. Journal*, July, 1888.

Sudden Death from Fear.

It is well known, says the *Wiener med. Presse*, May 27, 1888, that profound mental impressions are capable of producing, not only transient and lasting disturbances of the central nervous system, but even now and then sudden death. In the *Münchener med. Wochenschrift*, No. 20, Bollinger reports a case of sudden death from fear in a prisoner. It seems that a farm-laborer, sixty years old, in a fit of anger struck another man on the head with a pitch-fork, inflicting two wounds involving the skull. The injured man died of pyæmia. His assailant was imprisoned, and became extremely depressed and melancholy. On January 30 he did not seem to be quite well, but first complained of illness on the next day, when he had to appear before the jury as defendant. Here he became so miserable that he had to be carried away, and had the appearance of a man moribund. The skin was cold; there was no pulse, but repeated attacks of fainting. He was taken to the hospital, where he died in twenty-four hours. At the autopsy, his organs corresponded with the relatively good state of health which he had enjoyed before the occurrence just described, and no such changes were found, especially in the brain and heart, as could be charged as contributory to the direct cause of death.

Subsidence of Doubtful Tumors.

Dr. David W. Cheever, Professor of Surgery in the Harvard Medical School, in a paper read before the Suffolk District Medical Society, April 4, 1888, says that cases

of tumor are frequent in which an operation is not indicated, either on account of poor health, of age, or of the extent of the disease. He reports eleven cases in which tumors of a doubtful character subsided under the use of alterative medicines. The alteratives employed were iodide of potash, iodide of iron, bromide of potash, and occasionally mercury in some form, and arsenic.

In conclusion, he says that in the course of his practice he has once seen a case in which no arsenic could be tolerated, and twice cases in which the iodides could not be borne. He has had no success with Chian turpentine, but is now trying chloride of lime (an old remedy) for glandular enlargements.—*Boston Med. and Surg. Journal*, June 21, 1888.

Treatment of Ozæna with Naphthol.

At the recent congress of the French Society of Laryngology, Dr. Ruault recommended the treatment of ozæna with naphthol. He washes out the nasal cavities three or four times a day with a solution made by dissolving in a quart of water a teaspoonful of a solution of equal parts of borax and bicarbonate of soda, and a coffeespoonful of a solution of

Naphthol β	ʒ iii
Alcohol (90 per cent.)	f ʒ iiss

In very obstinate cases, the cavities are washed out, and then tamponed for fifteen minutes with cotton saturated in:

Naphthol β	ʒ iii
Tincture of quillaia	f ʒ iii
Distilled water	f ʒ xiii

The advantages of this treatment are a rapid disappearance of the odor, and a marked diminution of the secretion. The only objection to the naphthol is that, immediately after its employment, slight burning occurs, which very soon subsides.—*Wiener med. Presse*, June 17, 1888.

Glycerine Suppositories for Constipation.

The employment of injections of glycerine as purgatives is objectionable in persons with hemorrhoids or in those with irritable mucous membrane of the rectum which bleeds easily. When these conditions are present, the nozzle of the syringe has to be manipulated with great care. Boas has recommended (*Deutsche med. Wochenschrift*), as a substitute for the injections, suppositories of glycerine. He uses those made by Sauter, the largest of which contain one gramme of pure glycerine. These suppositories keep their shape and activity after being kept a week. Fifteen or twenty minutes after being inserted, there is an active call to stool, but it is unattended with tenesmus or other difficulty, and, as a rule, is quickly followed by an evacuation.—*Wiener med. Presse*, June 17, 1888.

Anthropometry.

At the Anthropological Institute of London, April 24, some interesting figures were, according to the *Lancet*, May 5, 1888, given in regard to the head-growth of Cambridge students. It seems that during the recent health-exhibition at South Kensington over nine thousand persons were measured in Mr. Galton's laboratory, and a comparison of these measurements with those of the Cambridge men gives a result strongly in favor of the latter, as the following table clearly shows:

	Height.	Weight.	Breathing capacity.	Pull.	Squeeze.
Cambridge,	68.9	153.6	254	83	87.5
S. Kensington,	67.9	143.0	219	74	85.0

These figures point to the high physical condition of the upper educated classes, and a comparison of these figures with those derived from the statistics collected by the anthropometric committee of the British Association shows that the average Cambridge student is distinctly above, and the average visitor to the exhibition about as much below, the mean of the general population in these particulars. The comparative brain-capacity was calculated by multiplying together the maximum length, maximum breadth, and height above a plane passing through the meatus auditorius and immediately beneath the superciliary ridge. The men were divided into three classes: A, first-class honors men; B, all other honors men; C, "poll" men and failures. It was shown that the heads in class A were distinctly larger than those in class B, and that while both gradually increased in size from the age of nineteen to twenty-five, the superiority was steadily maintained. In the case of class C, which started with a smaller head than either A or B, the size increased with much greater rapidity than in either of the other classes up to the age of twenty-two and a half, when the curve was found to cross that of class B; and at the age of twenty-five the size of the head of the average "poll" man, although considerably less than that of the "first-class" man, was slightly larger than that of the ordinary honors man.

Recent Mortality in New York.

The New York *Herald*, July 18, says: "The Sanitary Bureau reports that, for the week ending June 30, there were 1038 deaths registered in its office. This represents an annual death-rate of 35.37 per 1000 on an estimated population of 1,525,981. This is by far the greatest mortality in any one week reported up to that date during the present year. The total number of deaths from January 1 to June 23 was 18,684, and the weekly average was about 778, or 259 less than in the week ending June 30.

"This extra mortality of 259 in the last week of June probably represents the morbific effect of the hot summer weather, most fatal in cases of sunstroke, cholera infantum, and other enteric diseases. It is, perhaps, the most striking and conclusive demonstration that can be had of the necessity at this time for thorough sanitation of household premises and of great prudence in the care of the young. Though there has been an abnormal abatement of the deadly heat this month, its return with the dog-days will be more severely felt by contrast with the recent cool spell."

Gonorrhœal Ophthalmia.

At the meeting of the British Gynecological Society, June 13, 1888, Dr. Burnie read a note on gonorrhœal ophthalmia. Referring to his observations at the last meeting, he wished it to be understood that he looked upon gonorrhœal ophthalmia and purulent ophthalmia of infants as two distinct affections. The former occurred only in subjects suffering with gonorrhœa, never in second parties. It had never, in the experience of Dr. Burnie, affected both eyes, but might do so. It was not caused, in his opinion, by direct contagion, or else it would be much more frequent, but was due to metastasis, similar to gonorrhœal synovitis. The appearance of the eye was also different from that presented by eyes in which direct infection had taken place by means of towels, etc., as Dr. Burnie had repeatedly seen. The semi-ptosed condition of the eyelid was especially characteristic. In purulent ophthalmia of infants, the disease usually attacked both eyes, and was caused by direct infection.

Dr. Bell agreed very much with what Dr. Burnie said about gonorrhœal ophthalmia as distinct from purulent ophthalmia. He thought the former might be caused without direct infection, but that it might also be caused by direct infection. Diseases of metastatic nature in the eye were well known, such as iritis.

Dr. Woods remarked that he had never seen a case of gonorrhœal ophthalmia or rheumatism among soldiers, while he had seen several cases among officers. He thought this was against the view of direct infection and in favor of the metastatic nature, as direct infection would be more likely to take place among patients of a lower class.

Dr. Hime could not concur in Dr. Woods's conclusions. He thought direct infection was caused by want of care and cleanliness, both of which were exercised in the cases of soldiers much more than in the cases that came under observation in the ordinary hospitals. Experiments had proved that urethritis could be inoculated from gonorrhœal ophthalmia, but not from synovitis, and he thought gonorrhœal synovitis might often be identical with ordinary synovitis from other causes.—*Medical Press and Circular*, June 23, 1888.

Southern Surgical and Gynecological Association.

The meeting of the Southern Surgical and Gynecological Association will be held September 11, 12, and 13, 1888, at Birmingham, Alabama. A number of interesting papers have been promised by the leading surgeons and gynecologists of the South. The programme will be announced later. Dr. W. E. B. Davis, of Birmingham, is Secretary of the Association.

NEWS.

—Dr. H. L. Burritt, of Bridgeport, Conn., died July 11. He was graduated from Yale in 1844.

—Dr. Emil Grunmach, of the University of Berlin, has been granted the title of Professor.

—Dr. Valerian Tashkevich, Professor of Clinical Therapeutics in the University of Kharkoff, is dead.

—Dr. Fürbringer, of Amsterdam, has been chosen Professor of Anatomy in the University of Jena.

—Seventeen deaths from yellow fever are reported from Havana, Cuba, for the week ending July 7, 1888.

—Professor Virchow has been awarded the Boerhaave Medal for Anthropology by the Haarlem Scientific Society.

—Small-pox has made its appearance in the Polish quarter of Buffalo, N. Y. Eight cases were reported up to July 17.

—Dr. Robert D. Weeks died at his residence in Philadelphia, July 18.

—The American Gynecological Society will meet in Washington, September 17 to 19, instead of in Boston, as at first intended.

—Mr. Arthur Hare, principal assistant to Professor Chiene, of Edinburgh, has been appointed Professor of Surgery in Owens College, Manchester.

—A sanitary inspection of the public school-houses of Philadelphia is now in progress. A number of serious defects in drainage have been reported.

—A family, consisting of nine persons, was poisoned in Philadelphia, July 15. The source of the poison is supposed to be in some canned tomatoes. All have recovered.

—Professor Adamkiewicz has been promised increased clinical facilities in the University of Cracow, and, in consideration of this, has been induced to withhold his resignation.

—It is stated that some silly Parisian mothers have aroused the just indignation of the medical profession by painting the faces of their children, and dyeing their eyebrows.

—Dr. Bass Rawson, of Findlay, Ohio, who celebrated the 89th anniversary of his birth July 14, is one of three brothers, all practicing doctors. The oldest is 92 years old, and the youngest 84.

—At the commencement exercises of Union College, New York, June, 1888, the honorary degree of LL.D. was conferred upon Mr. Lawson Tait, F.R.C.S., Professor of Gynecology in Queen's College, Birmingham, England.

—The following cases of, and deaths from, infectious diseases were reported in New York City for the week ending July 17: Typhoid fever, 40 cases and 12 deaths; scarlet fever, 460 cases and 93 deaths; cerebro-spinal meningitis, 21 cases and 16 deaths; measles, 898 cases and 84 deaths; diphtheria, 481 cases and 147 deaths; small-pox, 13 cases and 2 deaths.

—The medical officer in charge of the Marine-Hospital Service at Ship Island Quarantine Station, Mississippi, reports that the captain and four men died of yellow fever on the Norwegian bark "Magnolia," on the voyage from Rio Janeiro. The vessel was bound for Pensacola, Fla., and is now undergoing quarantine at Ship Island, having been sent to that station by the Pensacola health authorities.

HUMOR.

He—"I see that old Mr. Bently was buried yesterday." Wife (shocked)—"Why, is old Mr. Bently dead?" He (who has just been "sat upon")—"The paper doesn't say whether he is dead or not; simply that he was buried yesterday."—*Life.*

Thunder and Lightning.—Lightning-rod agent (to boy)—"Is that your father lying there in the shade, sonny?" Boy—"No, sir; pa's away, an' me and ma is the only ones to home; that's a dead book-agent. D'ye want to sell ma anything?" "Thunder, no," said the lightning man.—*The Epoch.*

"I had my picture taken to-day," said little Christine. "I crossed my arms and leaned on a chair, and the picture-man put my head in some tongs." "Why, you must have looked like a lump of sugar in sugar-tongs," laughed papa. "Why, so I must have," said Christine, delightfully, "'cause the man kept saying: 'What a sweet little girl.'"—*Religious Record.*

Johnny was Anxious.—"Won't we get any dinner to-day, ma?" asked little Johnny McSwilligen, rather anxiously, as the congregation sang the closing hymn at the morning service last Sunday. "Of course we will, Johnny," whispered his mamma. "What put that question into your head?" "Why, everybody's singing 'We're going home, to dine no more.'"—*Pittsburg Chronicle-Telegraph.*

OBITUARY.

HORTENSIUS W. PURNELL, M.D.

We regret to learn that Dr. H. W. Purnell, an old subscriber to the Reporter, died July 3, 1888, at Hot Springs, Arkansas. He was born June 17, 1838, in Green County, Alabama. Dr. Purnell had been in ill health for some time, but none of his friends anticipated an early death. He abandoned his practice only a short time ago and went to the Springs. He was a graduate of the University of Louisiana, and for a number of years a resident student of the Charity Hospital in New Orleans. On the breaking out of the war, he joined the medical department of the army on the Confederate side, and (except for two months, while stationed in the hospitals at Holly Springs, Miss., until the evacuation of Corinth, after the Shiloh battle) was in the field medical service until the close of the war. In 1865 he moved to Memphis, and has since been constantly in practice.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

Dissecting Instruments,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers, with Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

College of Physicians and Surgeons

OF BALTIMORE, MD.

The Preliminary Course begins September 15th, 1888.

The Regular Session will open October 1st, 1888, and close about March 15th, 1889.

Attendance upon two full sessions is required for graduation.

The Clinical facilities of this school will be further increased by the new "City Hospital," which has a capacity of 300 beds.

For Catalogue, containing full information as to fees, etc., write to

THOMAS OPIE, M.D., Dean,

Cor. Calvert & Saratoga Sts., Baltimore.

THE

College of Physicians and Surgeons

OF CHICAGO.

Seventh Regular Session opens Sept. 25, 1888.

GRADED COURSE OF INSTRUCTION.

Unsurpassed Clinical Advantages.

FEES.—Matriculation, $5; General Ticket, admitting to all the lectures and including all practical work in the Laboratories, $60. For announcements and further information, address

WM. E. QUINE, M.D., Corresponding Sec'y,
3160 Indiana Ave.

Clinical Lecture.

FRACTURE OF THE FEMUR NEAR THE KNEE-JOINT, ILLUSTRATED BY CASES.

BY J. S. WIGHT, M.D.,

PROFESSOR OF OPERATIVE AND CLINICAL SURGERY AT THE LONG ISLAND COLLEGE HOSPITAL, BROOKLYN, N. Y.

When a bone is broken near a joint, the surgeon may meet with two difficulties: one of diagnosis, and the other of treatment. The difficulty of *diagnosis* is due to several facts: 1. The new point of motion, if there is one, is so near the joint that it may be mistaken for that of the joint itself. 2. There may be impaction of the shaft of the bone into the cancellous tissue, so that there is no new point of motion. 3. There may be a firm blood-clot on the broken surface of bone, so as to prevent the finding of crepitus. 4. There may be great swelling of the soft parts, obscuring the signs and symptoms of fracture. 5. The fracture may be incomplete, when there is neither crepitus nor a new point of motion. 6. There may have been a previous injury, whose results may be mistaken for the effects of the one that has recently taken place. The difficulty of *treatment* is also due to several facts: 1. When the end of a bone is broken, the neuro-muscular apparatus of the adjacent joint is irritated and disturbed, and the muscles that span the articulation contract with much force and persistency. These muscles tend to obstruct and prevent the reduction of the fragments of bone. And, when the fragments are reduced, they are very apt to be displaced again by the contraction of the irritated muscles. 2. I have often had opportunity to observe that a firm and tough blood-clot forms on the broken surface of cancellous bone; and I have many times noted the fact that this blood-clot prevents the satisfactory reduction of the bony fragments. I am reasonably certain that the organization of new bone does not either readily or frequently take the place of the clot that forms on the broken surface of cancellous bone. If this is so, we have one of the reasons why fibrous union occurs from time to time in the vicinity of joints. 3. The swelling of the soft parts will interfere with the hand of the surgeon reaching the bony fragments, so as to be in the way of an effort to reduce them. Even if the bony fragments could be reduced, the retentive appliances must for the most part fail to keep them in place, and, by the time the swelling is gone, the reduction of the fragments may have become impossible. 4. Anyone who has had much experience with fragments of bone will know that it is at times very difficult to reduce them from their new position to the one they came from. And this must be so, because it has required much violence to break them off and displace them, and because they are caught under strong bands of fascia, as well as resisting tendons, and also because they are under new lines of traction by the articular ligaments. In addition to these things, when there is comminution of bone, some of the fragments are beyond the reach of the surgeon's hand, and cannot be reduced; and, if reduction is possible, there is no way by which the fragments can be kept in place. 5. When the end of a bone is broken so that the lines of fracture extend into the joint, there will

be an increased quantity of synovia produced on account of the irritation. The consequence of this will be, that the synovia will get between the bony fragments and interfere with the formation of new bone. 6. Impaction of the shaft of a bone into the cancellous tissue of the end, such as the condyles of the femur, will certainly not interfere with treatment, if it is not disturbed by the surgeon. To break up an impaction may augment the displacements of the bony fragments, so that the deformity may be greater, and so that the disability may be increased in a marked degree.

That the facts and conclusions above stated have important relations to fractures of the lower end of the femur may be known from the following cases:

Case I.—On the morning of July 4, 1874, Mr. H——, about seventy-five years of age, had been drinking. He fell down the front steps of his house, and broke the lower end of his left femur. I saw him on the same day, and found a compound comminuted fracture. The fracture extended into the knee-joint, the condyles being split; the line of separation of the shaft was from below and in front, upward and backward—quite obliquely; the opening in the soft parts was large enough to admit two fingers, and had projecting out of it the sharp pointed end of the upper fragment, which was just above and in front of the patella. The lower fragments were displaced backward and upward; and the condyloid end of the thigh was considerably wider than that on the right side. This patient was put on a water-bed, and his injured limb was placed on a well-padded double-inclined plane, having a moderate elevation under the knee. Some extension or traction was made on the leg by means of a foot-piece on the splint. The position of moderate flexion and gentle traction reduced the lower end of the upper fragment from the wound, and restored the normal form of the knee to a considerable extent. A piece of soft clean cotton-wool was applied over the wound, and kept in place by means of a roller bandage. This piece of cotton-wool came off after about four weeks, leaving the wound well healed. In about eight weeks, this patient began to get up on crutches, and eventually had a very useful limb. There was considerable deformity about the knee. The motions of the leg were not extensive. It could be flexed nearly to a right angle with the thigh, while the extension was not so perfect as before the injury. It may be remarked that the double-inclined plane was so padded as to bring but very slight pressure on the popliteal space. Passive motion to a limited extent was made from day to day after one week. It was impossible to reduce the fragments accurately. The two condyloid fragments did not come into close apposition, and the sharp end of the upper fragment dropped partly between them. The union was fibrous. There was, finally, some motion at the seat of fracture; the motion of the knee-joint was impaired, and so the new point of motion seemed to add to the motion of the leg, and thus diminished the disability.

In this case, any attempt to put the limb in the straight position caused much pain, as well as marked displacement of the fragments; and traction in this position only augmented the difficulties. And, when the leg was fully extended, the lower end of the upper fragment came out of the wound again. But, when the leg was flexed, so as to make an angle with the thigh less than about 140 degrees, the pain became very severe.

Case II.—E. P., a clerk, sixty-one years of age, October 24, 1886, as he was walking, fell on his right knee, and was conveyed to the College Hospital, where I saw him, and found about two inches of the condyloid end of the right femur broken off nearly in a transverse direction. The lower fragment was displaced somewhat backward and inward. There was but slight swelling; the pain was quite severe. Traction on the foot, so as to extend the leg, caused pain, increased the deformity, and prevented reduction of the fragments. Flexion of the leg toward a right angle with the thigh tilted the lower fragment backward, made the lower end of the upper fragment prominent outward and forward, and reduction could not be accomplished. I constructed a double-inclined plane of wire-cloth. The angle of meeting of the two planes was about 155 degrees. The planes were well padded in such a way as to leave the popliteal space free from much pressure. The limb was laid on this splint. The pain was greatly relieved, and the fragments could be reduced, but would become displaced again on removal of the pressure made by the hands of the surgeon. A traction-weight of about four pounds was applied, and, when two angular side-splints were adjusted to the sides of the knee, so as to embrace the thigh, the knee, and the upper part of the leg, the fragments were kept well in place. This patient was discharged on the eighth of March, 1887, having good union

of the fragments. There was some deformity; there was considerable impairment of motion of the knee. After a year the patient could walk with a slight limp, but he still carried a cane. Considerable disability in his case will be permanent, though he has a useful limb.

Case III.—R. M., a laborer, sixty-four years of age, November 11, 1886, was going along the sidewalk and fell on his right knee. He was brought to the College Hospital, where I saw him soon after the accident. I found the right femur broken nearly two inches above the knee-joint. The line of fracture was quite transverse in an antero-posterior direction, and oblique from the outside downward and inward. The lower end of the upper fragment was displaced inward and forward. The lower fragment was displaced outward and upward, and tilted somewhat backward. The leg and lower fragment were rotated outward a few degrees, and there was some inward angular displacement. In moving the limb the patient suffered much pain. A traction-weight of six pounds was applied to the leg. A low double-inclined plane was put under the limb after it had been padded, so as to support the leg and thigh and prevent pressure on the popliteal space. Angular lateral splints were applied, so as to obviate, as far as possible, the lateral displacements of the fragments. Then the patient was quite free from pain. During the treatment of this case, it required constant attention to prevent the fragments from getting out of place. From time to time the fragments did get out of place and had to be reduced. It was four or five weeks before repair began to take place between the fragments, and, when the fragments were finally united, the union was for the most part fibrous, permitting some motion at the seat of fracture. This patient was discharged on the eleventh of February, 1887, with the knee-joint having about one-half its normal extent of motion. He walked with a cane and limped. The injured knee bent inward considerably more than the other.

Case IV.—A young sailor, about eighteen years of age, fell from a ship's rigging some twenty-five feet, and struck the deck with his left knee, the leg being semiflexed, and was treated by his captain, who pulled on the limb, for the purpose of "setting the bone" and removing the deformity. At the end of five weeks this patient was brought to the College Hospital, where I saw him. This was about the middle of December, 1886. I then made the following observations: The swelling of the soft parts had subsided; the motions of the leg had been impaired about one-half; the condyloid end of the left femur, as measured by the calipers, was about three-fourths of an inch greater in width than that of the right; the entire condyloid structure had been enlarged; the left femur was about an inch shorter than the right, according to careful measurement; the two legs were of equal length, and there was no mobility in the continuity of the injured femur. The best opinion I could form in regard to this case was that the lower end of the shaft, or diaphysis, of the left femur had been driven into the condyloid tissue, or the epiphysis, in such a manner as to expand it laterally, without complete separation of the parts. I was reasonably certain that there had been an impacted fracture. And it was fortunate, when the captain pulled on the leg, that he did not break up this impaction. If this accident had happened, there certainly would have been greater disability. This patient could walk with crutches, when he came to the hospital. He made some improvement, and left the hospital in two or three weeks.

Case V.—I saw Mr. L——, about sixty-five years of age, with Dr. Dodge, his attending surgeon. The patient had fallen down three or four steps, and struck on his right knee. The injury was very painful, and was accompanied by complete disability, in so far as walking was concerned. The flexion of the leg was impaired nearly one-half. We made a careful measurement of the transverse diameter of the condyles on both sides, and found that of the right about three-eighths of an inch greater than that of the left. In so far as the upper end of the tibia was concerned, the condyles of the right femur were more prominent than those of the left, as could be easily made out by feeling. To extend the leg completely increased the pain. The more the leg was flexed beyond a certain angle, the more he complained. When the leg and thigh met at an angle of about 165 degrees he appeared to suffer the least. Our conclusion was that the condyles had split vertically, so as not to be entirely separated from the femoral shaft. There had been an incomplete fracture of the condyloid end of the right femur. It would be impossible to reduce the fragments; traction would not be required; rest and an easy position of the limb were indicated. A double-inclined plane, having an adjustable angle, was padded so as to give only slight pressure on the popliteal space, and put under

the injured limb. This patient was up on crutches in about eight weeks, and, at the end of six months, could walk on a level nearly as well as ever. There was some enlargement of the lower end of the right femur, and the motions of the right leg were not as extensive as they were before the injury.

Case VI.—P. G., a laborer, forty-seven years of age, October 27, 1887, was run over by a loaded coal-cart, and brought to the College Hospital by the ambulance. On examination, I found he had a compound comminuted fracture of the condyloid end of the left femur, complicated by a severe contused wound of the leg below the knee. It is probable that the wheel of the cart went over his limb. The leg was rotated outward, and the condyloid fragments were displaced backward and upward, so that the limb was shortened about two inches. The knee was enlarged by the separation of the fragments, as well as by the swelling of the soft parts. The muscles on the thigh were very irritable, and contracted with much force, when the injured parts were examined. This caused much pain. An attempt to straighten the limb augmented the muscular spasm, and caused the lower end of the upper fragment to be carried forward in a marked degree. The wound was large enough to admit two or three fingers, but did not go directly down to the seat of fracture. The limb was put on a well-padded double-inclined plane, having an angle of about 145 degrees. The popliteal space was left as free from pressure as possible, so as to prevent injurious pressure to the vessels and nerve, as well as the bruised and broken structures. Two angular splints were applied—one on the outside and the other on the inside of the limb—embracing the knee and the seat of fracture; and a traction-weight of six pounds was applied to the leg. Then the reduced fragments were kept in good place, the muscles were quieted, and the pain ceased. In the meantime the wound had been made aseptic, and covered with an antiseptic pad. This case required frequent dressing, and from time to time the fragments got out of place and had to be carefully reduced. At the end of three months this patient had so far recovered that he could walk with a cane, and was discharged from the hospital, having a limb that had shortened an inch and a half, with the motions of the knee more than one-half impaired, with considerable enlargement of the condyles, and with more or less ligamentous union of the fragments of bone.

Case VII.—D. G., a boy, four and a half years of age, May 5, 1886, as he was walking along the sidewalk, his right leg went under him and he fell on his right side. He was seen by a surgeon, who said his leg was out of place, and who reduced it. On the following day I saw this boy with Dr. Stuart, the family physician, and we found the right femur broken near the middle and a diastasis of the lower epiphysis. Only the fracture at the lower end of the femur invites our attention now—for a diastasis is really a fracture. It is easy to see how the doctor could mistake the diastasis for a dislocation and make the reduction, but it is not so easy to understand how he overlooked the fracture of the shaft of the femur. We had no difficulty in reducing the fragments; it may be remarked that the pain was greater at the seat of the diastasis than it was at that of the fracture. The condyloid fragment inclined to go backward and upward, but was kept in place by means of a double-inclined plane of moderate height, aided by a traction-weight of about six pounds. Coaptation splints were applied, so as to embrace the three fragments, as well as the leg and the knee. This patient made a good recovery, having slight deformity and but very little disability.

Case VIII.—A laborer, fifty-seven years of age, fell on his right knee, October 24, 1887, and was at once brought to the College Hospital. On examination, I found his right leg abducted from five to ten degrees more than the left. There was slight swelling of the knee. The pain was severe. Lateral motion of the leg showed a new line of motion upward and outward through the external condyle, and the fragment could be felt moving up and down, and out and in, accompanied by distinct crepitus. The transverse condyloid diameter was three-eighths of an inch greater on the right than on the left side. It was impossible to flex the leg beyond a right angle with the thigh. The internal angular deformity was recent. In fact, the line of separation between the condyloid fragment and the rest of the bone could be readily traced with the finger. The injured limb of this patient was laid on a properly constructed and well-padded double-inclined plane, and an angular splint was applied to the outside—no traction-weight being used. The reduction of the fragment was good, and the patient was relieved from pain—so much so, that he came to the conclusion he was not seriously injured. I regret to say that the friends removed this patient from

the hospital at the end of four days, and that I have not been able to see him since.

The practical question in regard to the treatment of these cases may be stated somewhat as follows: When the condyloid end of the femur is broken more or less extensively, a moderate flexion of the leg on the thigh generally gives much relief from pain, enables the surgeon to make the best reduction of the bony fragments, and finally results in the least deformity and disability of the limb. And this proposition, which seems to be illustrated by the above noted cases, that have been taken from our note-book, may be reasonably well explained by the subjoined facts, relating to points of structure and function:

1. There are some points of importance touching the moderate flexion of the leg on the thigh. In the first place, when the leg is completely extended, the quadriceps extensor is fully relaxed, and the ham-string muscles become tense, as well as the gastrocnemius; the gastrocnemius pulls and tilts the condyloid fragments downward and backward, and the ham-string muscles pull the leg upward, and so augment the longitudinal displacement. In the second place, forcible flexion of the leg on the thigh makes the quadriceps extensor tense, so that it crowds the lower fragment upward and backward, making it a fulcrum, whose lower end will be forced forward and upward. Of course, the ham-string muscles will be relaxed, but that will leave the injured parts mostly in the power and under the influence of the irritated and contracting quadriceps extensor. Now, in the third place, it will be seen that moderate flexion of the leg on the thigh will put the flexors and extensors of the leg in the most desirable condition of antagonism, so that each set of muscles will act with a small degree of force, and then they will not greatly obstruct the reasonable efforts of the surgeon to reduce and keep the fragments in place.

2. The double-inclined plane will enable the surgeon to carry out the indications of treatment implied and contained in the facts of the above explanation. It is important, however, that the limb should rest on the pads under the leg and under the thigh. This point requires the especial care of the surgeon. The popliteal space may not be entirely free from pressure, but great care must be taken to keep this pressure always at a minimum. In fact, the surgeon ought to examine the condition of the popliteal space from day to day, and see that it is all right. A little soft cotton-wool will generally give gentle and elastic support to the popliteal space. One thing more in this place: The leg rests on the lower inclined plane. The body of the patient tends to sink into the bed. There is therefore traction on the upper femoral fragment. This takes place as the thigh moves upward on the upper inclined plane. But the leg rests on the lower inclined plane, which resists upward movement. This holds the lower or condyloid fragment downward. And the effect of these mechanical relations is in the direction of the reduction of the fragments of the bone, without undue pressure of the soft parts over or under the seat of fracture. If the lower inclined plane is properly padded, the upper part of the leg, as it rests on the pad, will sustain safely for a long time the pressure caused by this upward traction of the body on the thigh. This certainly agrees with my experience and observation. In some cases the application of this principle alone is competent and sufficient for proper treatment.

3. The reasons for the use of the traction-weight may not be so clear, but yet let us make the following explanation: A traction-weight of four pounds applied to the leg, as it rests on the lower inclined plane, would, in accordance with mechanical law, have its pull decomposed; in fact, there would be two pulls—one in the direction of the axis of the thigh, and the other at a right angle to this direction. The amount of the right-angled and backward pull would depend on the size of the angle at which the leg meets the thigh. After a careful estimate, drawn from actual measurements, I have found that about one-fourth of the traction-weight pulls backward at a right angle with the long axis of the femoral shaft, and that the remaining three-fourths of this weight pulls in a direction from the hip to the knee. On this supposition, we have three pounds of traction operating to keep up the removal of the longitudinal displacement of the condyloid fragment; and then there is one pound of backward pull, operating to cause angular displacement of condyloid fragment backward. On first view, this backward pull is objectionable; but yet it is not very great, and alone could not produce any marked displacement and deformity. In fact, it will be seen that it will be mostly employed in tilting the lower end of the condyloid fragment backward; and this will truly be advantageous, since it will tend to counteract the usual backward and downward displacement of the upper end of the condyloid

fragment. Hence, in any way we may view the traction-weight, as we have recommended its use, its effects must be, in the main, practically good and desirable.

The result in a case of fracture of the condyloid end of the femur, both on theoretical and practical grounds, which are dependent on structure and function, may be stated in the following way: There will be more or less deformity caused by displacements and the products of repair. The products of repair will be found between and about the fragments, as well as in the joint itself; and there will be impairment of function, whose extent will depend on the enlargement of the injured condyles, the inflammatory changes in the ligaments, and the adhesions that form in and about the knee-joint. In the majority of cases, there will be considerable disability of the limb, for the motions of the knee-joint will be limited and locomotion will be impaired. There can be no general standard of disability, and it will have to be estimated and rated in each case, and the only question that would be difficult would arise in regard to treatment.

COMMUNICATIONS.

TREATMENT OF PERITONITIS WITH PILOCARPINE.

BY JAMES Y. SHEARER, A.M., M.D.,
SINKING SPRING, PA.

I have read very little of interest on this subject—peritonitis—for many years. The only information we have thus far been favored with is from our authors who, as a general rule, go over the old routine of practice. Peritonitis is looked upon as a dangerous, and even fatal, disease. Every physician who meets such a case is always in doubt as to the final result. I have seen cases of peritonitis in which the patients were treated with sulphate of morphia and opium in very large doses, and yet were gradually sinking all the time, and finally died very suddenly. Calomel and opium were at one time considered to be the great remedies, but experience has since shown that the opium was doing the work; since then, opium has been very highly recommended in this disease, and yet from experience we learn that a large percentage of its victims die. Dr. Flint, speaking of the gradual change in the treatment of this disease, says on page 510 in his "Practice of Medicine": "The change consists, first, in the disuse of blood-letting and cathartics, and, second, in relying mainly on the use of opium." Dr. Watson, in his lectures on the Principles and Practice of Physic, forty-four years ago, recommended blood-letting, calomel, and opium in strong terms, and stated that "it is extremely desirable in these cases to obtain, as speedily as possible, the specific influence of mercury upon the system, by calomel and opium." Years ago, writers on this subject recommended both mercury and opium. Gradually the mercury was dropped, and now opium is looked upon as the principal agent in the treatment of this dreadful malady. It is within a few years that I resorted to the same remedy, and, am sorry to say, not with too great satisfaction; but at this time I am pleased to be able to present to the profession a treatment for peritonitis which will not only give satisfaction to some isolated few, but which will, in my opinion, become the recognized remedy for this disease in the near future throughout the civilized world. One year ago I intended to write an article on this subject, but I refrained, as I desired to give it a full, fair, and impartial test before so doing.

In 1885, I changed my treatment of peritonitis, giving, instead of opium, nitrate of pilocarpine From the nature of the drug, and from its action, as results from its use in other cases unmistakably showed, I concluded that pilocarpine would accomplish in peritonitis what nothing else known to the profession would. I accordingly determined to use it.

Case I.—On May 6, 1885, Mrs. J. H., 25 years old, was delivered of a very large child: a face presentation and a very difficult labor. On the day following, I saw her twice. She then already had symptoms of peritonitis. On May 8, I found her very sick. She was weak and had a very high fever, with a pulse of 120. Her abdomen was very much swollen and distended, and very sensitive to the touch. She had great pain. Her urine was scant and high-colored. Her skin was dry, and she had a great thirst for water. She also had vomiting-spells. There was no mistaking the disease I had before me—a genuine case of peritonitis. I ordered the following:

℞. Pilocarpinæ nitratis . . . . . gr. 1
Aquæ . . . . . f℥j
Mix.

Of this she took a teaspoonful every four hours in a little water. The day following—

May 9—I found her much improved. The first dose checked the vomiting, and after the third dose there was profuse perspiration. I also found an increase of urine, and the patient had more rest.

On May 10, I saw the patient and found a decided improvement. She had no pain, and the swelling of the abdomen was very much reduced. She also had a natural movement of the bowels. I then ordered the medicine to be given every five hours instead of four.

The day following—May 11—she was doing so well that I ordered the medicine to be given every six hours. On May 12, she was entirely out of danger. She took nourishment and was fast recovering. On May 15, I pronounced her well

Case II.—Mrs. S. B., aged twenty-two years, took sick on November 18, 1887, of peritonitis, the result of a fall. I was called to see her November 21, and found her pregnant, having gone about four months. Her abdomen was very much swollen and sensitive. She vomited everything that was given to her. Her pulse was 130, and she had great dryness of the tongue. She was so weak and swollen that she was obliged to assume a half-lying position. She had great pain in her abdomen. I prescribed for her the following:

℞. Pilocarpinæ nitratis . . . . . gr. 1
Aquæ . . . . . f℥j
Mix.

I ordered a teaspoonful every four hours, in a little water.

I saw her again the following morning, November 22, and found her doing much better. She had had no vomiting after taking the first dose of the medicine. Her skin was moist, and she could take a little nourishment. She passed her urine freely. Her pulse was 108.

I saw her November 23, and found her improving. The swelling of her abdomen was fast subsiding. Her pain was less, and the sensitiveness of her abdomen was decreasing. She had a natural movement of the bowels, and took nourishment quite freely. I then ordered the medicine to be taken every six hours.

I saw her again on November 25. She was doing so well that I considered her out of all danger. But she still continued to take the medicine.

On the 28th, I saw her again, when I pronounced her well.

I have since had a number of other cases of peritonitis that I might report at length, but suffice it to say that, by using the same remedy, I had the same happy results. But one case I feel constrained to notice more fully, as the patient was a male, and the circumstances possibly more striking.

The patient was a man about fifty years old, who had a very severe fall on the abdomen, in his barn. He had called in another physician in my absence, who had treated him several days before I was called in. When I first saw him, he had great abdominal tenderness, vomiting-spells, dry tongue, great thirst, and dry skin—a clear case of peritonitis. I at once administered pilocarpine nitrate, as hereinbefore stated, and the medicine acted so effectively and charmingly that I felt it my duty to make a report of it to the profession Since using this remedy, I have not lost a single case of peritonitis. Practitioners of medicine too frequently make mistakes in following practices and book-recommendations long exploded, and fashioned after mistaken sentiment and error. Too little attention is paid to therapeutics. Medicines are poured into the patient without regard to their actions. In this way no profit can be derived from experience. To fulfill the duties of a practitioner of medicine requires the careful observation of individual cases in all their bearings, a thorough examination of all circumstances, causes, and results, and that this information be so digested as to enable him to have the benefit of it in subsequent cases of similar character. This I call experience. I have followed this course for over a quarter of a century, and the satisfaction it yields is inexpressible. In this way I came to use pilocarpine in peritonitis. This treatment did not come to me recommended by any author. I have used it of my own accord, believing that from the nature of the medicine I could accomplish with it what I could not do with any other agent. Thus far it has uniformly given me such excellent results that I have no fear in recommending it to the profession, and bespeaking for it the highest merits in the treatment of peritonitis.

—The *Weekly Abstract of Sanitary Reports* states that the American brig "Teneriffe," from Havana, arrived July 22, at the Delaware Breakwater Quarantine Station, with two cases of yellow fever on board. One man died during the passage. The sick have been admitted to hospital, and the vessel placed in quarantine. Since the admission of the first two cases, the captain, who had remained on board, was taken sick, and at once removed to hospital.

THE TREATMENT OF POTT'S DISEASE.[1]

H. LONGSTREET TAYLOR, A.M., M.D.,
ASSISTANT TO THE CHAIR OF CLINICAL SURGERY, AND ASSISTANT SURGEON IN THE SURGICAL CLINIC OF THE MEDICAL COLLEGE OF OHIO, CINCINNATI.

The mechanical treatment of Pott's disease of the spine has practically not advanced since Sayre first applied the plaster jacket and at the same time connected his name almost as inseparably with this disease as the immortal Pott has done.

One question of great practical importance in this treatment is, shall this support be continuous, or may we trust to position during the night, when the jacket becomes most wearisome to the sufferer? To borrow a comparison from the younger Sayre, must the parts be kept as constantly and as carefully in splints as a fractured bone? From clinical experience and observation, I think not, if an exception is made of very acute and progressive cases. If a properly fitted appliance is worn during the day, from just previous to arising to immediately after retiring, then the weight of the body is at no time transmitted through the vertebral column, and the diseased part is relieved from pressure. The patient that sleeps on a hard mattress, without a pillow or with but a very small one, gains as much from this position during the night as from his mechanical support throughout the day. If the apparatus is to be taken off at night, the plaster-of-Paris jacket can not be used; it must be substituted by a movable corset of steel, leather, felt, or some other material. Personally I am very well satisfied with the leather jacket. It is cheap, it can be made by the surgeon himself without the aid of the instrument-maker, or by calling on the latter to apply the finishing-touches only, after he has adapted it to his patient; it is light, durable, cleanly, well ventilated, and, above all, accomplishes its purpose. A leather corset, laced on tightly each morning, will be found to fit more accurately than a plaster-of-Paris jacket. The latter is very apt to expand slightly while setting, and so from the first may not be an exact fit. The laced corset can also adapt itself to changes in the body due to variations in weight.

The leather jacket is so simple that a person without the slightest idea of mechanical principles can apply it perfectly. This is not true of steel supports. To obtain the best results with these, they should be under the control of a person of some intelligence; but, outside of hospitals, we have to rely upon the family, and only too often they are not capable of understanding why such minute directions must be obeyed, or of following them if they would.

This melancholy picture is illustrated by the history of Jim F. I first saw him in October, 1886. The symptoms of the disease were very marked; rigidity of the spine, local pain, deformity, unwillingness to walk, and the characteristic method of picking up articles from the floor.

The hump was about the middorsal region. There was no history of a trauma. As the mother could not be trusted to make the proper use of a movable corset, Sayre's jacket was at once applied. After this the symptoms were not so severe, but the child was feverish and restless. At the end of a month the parents, who could not see their child tortured in that manner, insisted upon taking off the jacket.

But the child clamored for it, now that he had learned its value, and, out of sympathy for him, I once more took charge of the case and fitted a leather corset. The result justified my fears. The patient grew worse from week to week on account of bad nursing and neglect. He died from the heat in the summer of 1887, during my absence from the city.

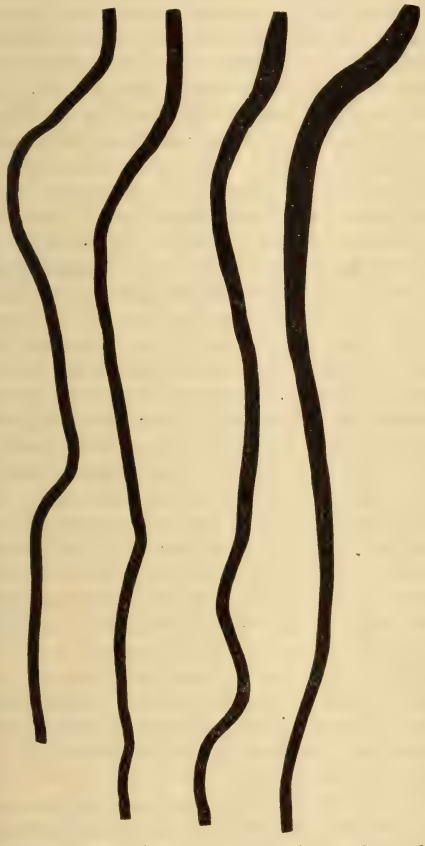
In a hospital the child might have been saved, but such care as he received from his mother would have rendered any treatment nugatory. In such families it should always be Sayre's jacket, and never a movable one.

With the intelligent assistance of the parents, it is another matter altogether. Geo. J., whose present condition is shown by the diagram Fig. 1, was just recovering from measles when his parents noticed something wrong. When I first saw him in March, 1887, quite a prominent hump was situated just below the seventh dorsal vertebra. He was then three and a half years old. He was at once given a leather jacket. Since that time he has had scarcely a bad symptom, and, a few weeks ago, walked two miles without a complaint. The vertebræ seem to be solidified, but the child will not give up the corset. It is difficult to decide when the proper time has come to withdraw supports. Alexander says that no spine can be considered cured until a post-mortem has been made, which sounds as though he would condemn these unfortunates to the wear-

[1] Paper read before the Ohio State Medical Society, June 15, 1888.

ing of braces and supports all their lives. While the disease is very chronic, as is caries of any of the spongy bones, yet in some cases its advance finally ceases, and after the lapse of time nothing remains as evidence of its former presence except the destruction that it has wrought. This patient has had no fever, no cough, has not lost flesh, there is apparent anchylosis, and yet he refuses to go without his support.

FIGS. 1, 2, 3, 4.



NOTE.—These figures are lead wire tracings of the spinal column and part of the skull. They all end at the sacrum. Figs. 1 and 2 pass above the occipital protuberance, but Figs. 3 and 4 do not.

The patients were standing erect with no support.

This difficulty is, however, not always met with. Harry D., a boy of about the same age, a tracing of whose back is shown in Fig. 2, wore his jacket for fifteen months; he had had symptoms for nine months before I saw him, but not the slightest difficulty was experienced in taking away his support when the time came. His case is of interest because a second kyphosis developed in the lumbar region. There was no history of a trauma. He is now suffering with general tuberculosis.

In Fred H.'s case, however, Fig. 3, a trauma seems to have been the starting-point. He was hurt in the back during an encounter with a goat, and from that time his symptoms dated. Before many weeks passed, the surgeon who was called applied Sayre's jacket. The family compelled him to remove it in a few weeks, and he gave up the case. About a year after the accident I was called and made a leather jacket for him. The hump was at the junction of the dorsal and lumbar vertebræ. He soon began to run about and play, which he had not done for a long time. He wore the jacket fourteen months, when it was taken off. The hump is more prominent than it was, but this is due in great measure to the sharp compensatory curves in its immediate neighborhood.

The most interesting case of all is that of Gus. D., Fig. 4, now 14 years old. When he was 11 years old, he began to complain of obscure pains, would not play with other boys, and slept badly. An examination revealed rigidity of the spine and a contracted and painful condition of the right psoas muscle. The boy leaned to that side when he was obliged to move around, and held the thigh fixed in a semiflexed position at all times. There was a fluctuating swelling, as large as a walnut, just above the crest of the ilium, at the outer edge of the quadratus lumborum muscle. This was aspirated and a small quantity of thick pus drawn off. There was tenderness to pressure over the lower dorsal vertebræ, and, while the jacket was being made, the spine of the eleventh dorsal vertebra began to grow prominent. The jacket was applied and rest ordered, while extension was made by means of the weight and pulley to the right leg. This last was discontinued after three weeks, as the irritability and sensibility of the psoas had disappeared. The jacket was worn for six months, when it was removed, and to-day a slightly exaggerated lumbar curve is all that can be seen. The boy is strong and active.

Many surgeons condemn interference with abscesses connected with Pott's disease; but whether this objection is founded upon improper methods of operating and after-treatment, or upon good and sufficient surgical principles, is very doubtful. It is argued that these abscesses frequently undergo spontaneous absorption; but, with Mr. Edmund Owen and others, I think that this probability is very small, and that

a statistical study of a large number of carefully observed cases would probably alter the opinion of the profession upon this point. Mr. Owen says: "In my own experience, this happy contingency (spontaneous absorption) has been so rare that I do not regard it as within the range of practical therapeutics."

Disastrous results have followed puncture in the neighborhood of Poupart's ligament, and will continue to do so, because the opening is made at the end of a long sinuous tract, with pouches in which the retention and fermentation of the discharges must occur, and which the most careful disinfection and drainage from the groin alone cannot reach.

It has been proposed, in order to overcome these difficulties and to rescue the patient from the dangers of a tedious and extensive suppuration, to make a counter-opening at the other end of the abscess, and, by free irrigation throughout its length, hasten its obliteration. A number of surgeons have followed this practice, and their success has certainly been most gratifying. It is unnecessary to recite the cases to this society, but the names of such surgeons as König, Wood, Israel, Treves, Dollinger, and others must certainly command attention.

This was the first step in advance from the expectant plan, and opened the way for the second one, the local treatment of the diseased vertebræ themselves. In 1882, Israel opened a large abscess in the lumbar region. Exploring with his finger, he felt that the twelfth rib was carious to a considerable extent, which part he at once resected. The finger now passed on readily to the body of the twelfth dorsal vertebra, in which a large sequestrum was found and also removed. In loosening it, the membranes of the cord were exposed and a collection of pus evacuated that had been compressing the cord. The sequestrum consisted of at least half of the body of the vertebra. From that time, the patient was relieved of pain. He died with empyema some weeks later, when the abscess-cavity was found much shrunken, while healthy granulations occupied the seat of the sequestrum.

In 1884, Treves reported to the Royal Medical and Chirurgical Society, London, three cases in which he had examined, through a lumbar incision, the bodies of the lowest dorsal and the lumbar vertebræ. In one case he removed a large sequestrum one inch by half an inch, and the patient's recovery was rapid and complete. In another he removed simply necrotic sand and detritus, but had the satisfaction, upon making an investigation after death from general tuberculosis some months later, of finding the previously denuded bone covered and the abscess nearly closed. A third case was simply exploratory at the seat of an old lumbar kyphosis, where, however, nothing was found. The patient recovered.

This is certainly scientific surgery. It is but the same practice that has been so successful in analogous conditions in other situations, where no one would now for a moment call its propriety into question and where the expectant plan of treatment amounts almost to criminal carelessness.

We are told that the destruction of bone in this situation is of such an essentially slow and chronic nature that it should not be interfered with. But is this statement not an argument for interference? Of whatsoever variety the caries in the vertebræ may be, whether due to a localized tuberculosis, the effect of a trauma, or the result of a pyæmic embolus, the process of healing can be greatly shortened, or induced in cases in which it would otherwise never occur, by the application of the sharp spoon, followed by a thorough disinfection of the diseased cavity and the surrounding tissues. Drs. Thos. G. Morton and Wm. Hunt, editors of the article on Orthopedic Surgery in the Annual of the Universal Medical Sciences, just published, say: "Pott's idea of treatment was based upon attacking the disease *in situ*. Who knows but what in these days of antiseptic surgery we may practically return to his methods in a much bolder way? Such treatment would be positive and based upon sound pathology, while the most that can be said of the present method of treatment, in all its varieties, is that it is expectant."

In order to reach the bodies of the lumbar vertebræ and the last dorsal, an incision is made at the outer edge of the erector spinæ mass. Some of the fibres of the latissimus dorsi muscle must be divided, and also the superficial layer of the lumbar fascia. This opens the fascial sheath around the erector spinæ mass, which can then be readily retracted toward the median line, while the posterior part of the sheath, the middle layer of the lumbar fascia, is incised near the tips of the transverse processes of the vertebræ. If there is a large abscess, it will now present; if not, a short dissection with the scalpel-handle along the transverse process leads to the body of the vertebra, which can be examined with the finger.

The results of the few operations that have been made are the best testimonials of its worth.

I have long thought that this operation should not be limited to the lower end of the column, where its advocates confine it. Recently I have made quite a number of dissections in order to see whether the bodies of the dorsal vertebræ are not accessible to the surgeon by a short and safe dissection. After finishing my investigations, I found that Dr. Thos. Laffan had suggested to the Royal Academy of Medicine of Ireland, at its meeting last January, that this operation should be extended to all of the dorsal vertebræ, and he deserves the credit of being the first to propose this extensive application of local surgical treatment.

My conclusions from the dissections that I have made on both adult and infant subjects are, that the bodies of all the vertebræ are accessible to the surgeon, and that there is but little danger of opening the pleural cavity.

The best method is to make an incision about three inches long just external to the transverse processes of the vertebræ, down to the ribs. In the dorsal region, the erector spinæ mass cannot be retracted as readily as in the lumbar region, as the serrations of the different muscles inserted into the ribs render this impossible. Therefore an incision through the muscle in the direction of its fibres is better than retracting. Subperiosteal resection of from half to three-quarters of an inch of the rib, in the centre of the incision, is the second step. One end of the resected piece should be as near to the articulation of the rib with the transverse process as possible. The third step is the dissection of the parietal pleural and subpleural tissue from the head of the rib and the side of the vertebra or vertebræ to be examined. This has always been easily done with a blunt instrument and invariably without opening the pleural cavity. In the child, on several subjects, I could readily pass the tip of my finger to the opposite side of the vertebra, and could examine as many as four vertebræ from one opening.

It is readily understood that, when an abscess-cavity exists, this subpleural dissection will be very short, and the danger of opening the pleural cavity be reduced to a minimum, by the fact that it will be found to have been obliterated by adhesive inflammation in the vast majority of cases.

Having exposed the seat of the disease, the bone can be scraped and gouged with small sharp spoons, set at different angles to their handles; sequestra can be extracted, which, by pressure upon the cord or by the retention of the products of suppuration, may be the cause of paraplegia; the pyogenetic membrane of the abscess-cavity can be destroyed and removed; the cavity can be thoroughly disinfected, and the recuperative power of the patient given an opportunity to assert itself.

This operation should undoubtedly be restricted to cases in which all the symptoms point to an abscess. Whether, when its value has been determined, it may or may not become the routine practice in every case as soon as the diagnosis has been made, cannot now be predicted. Should this future be in store for it, a shortening of the time required by the present expectant plan of treatment to weeks, instead of months or years, a lessening of the deformities due to great loss of bone, and a great reduction of the danger of constitutional infection in tubercular cases are among the brilliant possibilities of the local treatment of Pott's disease.

UNUSUAL CASE OF FECAL OBSTRUCTION.

NOTES FROM THE PRACTICE OF DR. J. M. KEATING.

In 1880, A. B., æt. 20, an unmarried woman, came under Dr. Keating's care. The patient had been a chronic invalid for several years, having gradually grown worse despite all treatment. At the first visit, the patient was pulseless and unconscious—though she could be occasionally aroused—with cold clammy skin and marked emaciation. A history of gradual emaciation, constant vomiting, excessive pain radiating from the epigastrium to the back, and vomiting of blood, was elucidated. The abdomen was enormously enlarged. Under hypodermic injection of digitalis and whiskey, the patient revived somewhat. An examination was then possible, which revealed a mass of solid matter, simulating an enlarged spleen, extending from the splenic region to the left iliac fossa, and as great an enlargement on the other side, due to excessive tympany. An examination of the bowel revealed a stricture of the rectum about four inches from the outlet, so small as to make it impossible to introduce the point of the finger. The uterus was retroflexed and retroverted, bound down by adhesion, and, in fact, pressing so forcibly down upon the

bowel as at once to give the impression that it was this and an inflammatory mass, with possibly a displaced ovary, that had been the cause of the stricture.

After careful manipulation, a long male catheter was finally passed through the stricture and into the bowel, through which some warm water was injected and very putrid material was drawn off. Dr. D. Hayes Agnew now saw the case in consultation, dilated the stricture with bougies, and drew off a large amount of the most putrid matter, which diminished the tumor in the region of the descending colon.

It was afterward learned that the patient had suffered intense irritation by the administration of croton oil some years before the patient came under Dr. Keating's care.

After the dilatation, enemata for a time kept the bowels open; but in a short time all the symptoms returned, with scanty evacuations consisting of mucus stained with feces. She retained no food whatever for days at a time, and was supported almost entirely by nutritious enemata. Menstruation was irregular, remaining absent for periods of four or five months, and then occurring once or twice. The uterus was straightened, and the adhesions softened or removed by means of tampons and mechanical treatment, but, all her other symptoms continuing in their severest form, Dr. Agnew was again called in consultation, January, 1883, and forcible dilatation of the stricture was practiced. Large quantities of mucus were passed, but no feces. Food was retained by the stomach for a short time. She did not now vomit any blood, but all the other symptoms again returned.

It was now determined to attempt gradual dilatation of the stricture; this, however, was attended with only partial success, as the feces were passed with difficulty and presented evidences of much compression; however, she was able to retain small quantities of food; but violent headaches developed, with excessive and uncontrollable vomiting, sometimes of fecal matter. This gave some relief, especially to the tympany, which was becoming an alarming symptom.

On February 24, 1887, the operation of colotomy was performed by Dr. John H. Packard,[1] the then consultant, but the colon was not opened. On March 17, 1887, the cæcum was opened by Dr. Packard, who stitched the edges of the opening to those of the wound in the skin. The patient was relieved by this procedure for a time, but great difficulty arose in keeping the opening patulous, it finally closing down to almost a pin-point in spite of all efforts to the contrary, Dr. Thomas R. Neilson devoting much time and attention to this matter.

The case has been a very puzzling one all through, and has at various times been examined by the following physicians as consultants or attendants: Drs. D. Hayes Agnew, Theophilus Parvin, Charles B. Nancrede, J. H. Packard, W. A. Edwards, and T. R. Neilson. Finally, on June 5, 1888, Dr. J. M. Keating performed an exploratory laparotomy, assisted by Drs. Nancrede, Neilson, Edwards, Thomas, Bonnaffon, and Mr. Clarke. The patient, as in all the other operations, was first rendered insensible by the administration of nitrous oxide, after which anæsthesia was maintained by sulphuric ether. The uterus was found to be retroverted, and its fundus and posterior wall were roughened by old adhesions, which had been diagnosed by rectal and vaginal examinations and had improved and softened under treatment. The left ovary was congested and lying in the cul-de-sac behind the fundus. The colon, as far as could be ascertained, was normally situated and histologically intact. The rectal stricture was found to be entirely within the calibre of the tube, and not one caused by any growth, pressure, or adhesion without the gut.

The patient did well, recovered nicely from the section, and is now up and about, doing well and gaining strength. The stricture is being dilated. Several days ago she passed some large scyballæ. It is a curious fact that a large injection of warm water remains in the bowel, except a small portion which oozes out of the cæcal opening. The patient apparently absorbs this water. The rectum below the stricture is simply a large sac, completely paralyzed, and feels much like the dead bowel on the post-mortem table.

[1] For account of operation, see Dr. Packard's paper in Trans. Med. Soc. of Penn., vol. xix, 1887, p. 75.

The Glass-Eater.—The Philadelphia *Ledger* says that the glass-eater, who used to amuse the visitors to a number of dime museums throughout the country, often had a *pane* in his stomach, but he has now developed a full-fledged inflammation of that organ as a result of his diet. The latter, he explains, was not glass, but a composition of gelatine and soluble silicate, which exactly counterfeited glass and was supposed to be harmless. That it was not entirely so is shown by his present sickness.

Society Reports.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

TWENTY-FOURTH ANNUAL MEETING, AT NEW LONDON, CONN., JULY 18 AND 19, 1888.

(Specially reported for the Medical and Surgical Reporter.)

First Day, Wednesday, July 18.

The President, Dr. Wm. F. Norris, of Philadelphia, in opening the meeting, referred to the losses of the Society by death during the past year. Dr. H. D. Noyes read a brief memoir of the late Dr. C. R. Agnew, and committees were appointed to prepare similar memorials of Drs. E. G. Loring and Joseph Aub.

The Division of Membranous Opacities of the Vitreous.

Dr. C. S. Bull, of New York, had done this by introducing a needle or narrow cataract-knife through the sclerotic just in front of the equator of the eyeball, and below the insertion of the external or internal recti muscles, usually the former. This was done under antiseptic precautions, and a protective bandage applied for two or three days. The reaction was commonly very slight. He had performed the operation on 17 eyes. None had been left the worse for such interference; 14 had vision improved; in 11 it was doubled or more than doubled. The best results were quite equal to those of very successful cataract extractions. There was usually some immediate improvement, which often went on increasing for days or weeks. In nearly all of these cases there was a history of previous deep inflammation of the eye; but it was important to wait until all inflammatory symptoms had subsided, before attempting such surgical interference.

Dr. W. F. Mittendorf, of New York, thought that vascularity of such a membrane should contra-indicate operation. Vascular membranes often disappear spontaneously, and hemorrhage from divided vessels would be liable to interfere with the result.

Pulsating Exophthalmos, cured by Ligation of the Common Carotid.

Dr. F. Buller, of Montreal, had seen two other cases of this character in which death had occurred from epistaxis, one after ligature of the carotid, the other without any attempt in that direction. In the latter there was found a direct communication between the internal carotid and the nostril, due to fissure of the base of the skull. The special subject of this report was a man aged 20, who had fallen, striking the right side of his head. On regaining consciousness, a loud beating sound was noticed in the head. There was great swelling of the right side of the face, and, when this subsided so that the right eye could be opened, diplopia was noticed. The pupil was dilated, and the eyeball displaced outward five-tenths of an inch, and forward six-tenths of an inch. There was strong pulsation and a loud bruit, which ceased on compressing the carotid. The right common carotid was ligated at its upper portion. The wound was found entirely healed when the dressing was first opened, on the tenth day. The swelling was immediately diminished; bruit and pulsation ceased at once. Vision improved from 20-100 to 20-20. A slight prominence of the eye was the only remaining symptom.

Dr. J. O. Tansley, of New York, and Dr. C. J. Kipp, of Newark, narrated cases of pulsating exophthalmos in which great improvement had occurred while using small doses of potassium iodide.

Dr. S. D. Risley, of Philadelphia, had seen a case in which cessation of pulsation and bruit occurred after three periods of compression of the carotid until faintness was produced.

The Measurement of Astigmatism with the Ophthalmometer.

Dr. S. M. Burnett, of Washington, had measured with the ophthalmometer of Javal the refraction of the healthy cornea in 576 eyes belonging to 301 persons. From the results of these examinations he concludes: That in corneal astigmatism the vertical meridian is, with few exceptions, the most strongly refractive; that many cases of lenticular astigmatism are due to the oblique position of the lens; that the corneal astigmatism expresses in a vast majority of cases the general astigmatism, both as to degree and axis, and therefore this instrument furnishes one of the best means of diagnosticating that anomaly; that astigmatism is not more likely to lead to progressive myopia than any other form of ametropia.

Dr. H. D. Noyes, of New York, confirmed Dr. Burnett's estimate of the instrument. Its findings without atropia, in the immense majority of cases, correspond to the refraction determined under atropia. It sometimes shows that the meridians of greatest

and of least curvature are not perpendicular to one another, so that the astigmatism is not capable of perfect correction. It shows that variations in the pressure of the lids or in the tension of the recti muscles may cause notable variations in the corneal refraction, and sometimes the cornea is so thin that there is a distinct pulsation of the corneal reflex.

Dr. C. Koller, formerly of Vienna, now of New York, could add testimony to the value of the ophthalmometer. He thought the meridians of greatest and least refraction were sometimes not perpendicular because of a very large angle alpha.

Dr. B. A. Randall, of Philadelphia, called attention to the fact that Dr. Burnett's statistics as to the relative frequency of various forms of astigmatism differed radically from statistics obtained from the examination of eyes under a mydriatic.

Progressive Hyperopic Astigmatism.

Dr. J. B. Emerson, of New York, reported a case under observation several years, in which this error of refraction had gradually increased from nothing, until it required to correct it R. + 1-9 cyl. axis 165°, L. + 1-18 cyl. axis 180°.

Instruments.

Dr. E. Jackson, of Philadelphia, exhibited a new form of cataract-knife, in effect a combination of the Graefe and Beer knives. It combined the perfect control of the puncture and counter-puncture of the former, with the smoothness of incision, retention of aqueous, and assistance in fixation of the latter. With it, the incision was commenced as with a Graefe knife, and completed by a single forward thrust, as with the Beer knife.

Dr. J. O. Tansley showed forceps for compressing the lachrymal puncta and preventing the entrance of strong mydriatic solutions that it was sometimes necessary to use in the eye, and which, when absorbed from the lachrymal passages, the nose, or the throat, were liable to cause constitutional symptoms. He also exhibited hollow lachrymal styles and tubes for injecting the lachrymal passages.

Dr. Mittendorf, for injecting the lachrymal passages, attached the perforated canula to a piece of rubber tubing, and not to a syringe.

Dr. S. Theobald exhibited a set of lachrymal probes made of aluminium, which is a light, non-oxidizable, very smooth or slippery metal.

Œdema of the Choroid and Retina.

Dr. E. Jackson reported the case of a young man who suffered a bruise of the eyeball. The ophthalmoscope showed œdema of both choroid and retina, which disappeared as the eye went on to recovery. Water-color sketches, showing the appearances presented, accompanied the report. There was also a myopic astigmatism of 0.75 D., which entirely disappeared in three weeks.

Symptomatic Myopia.

Dr. W. F. Mittendorf called attention to this kind of myopia, and reported cases of its occurrence in connection with commencing cataract, glaucoma, choroiditis, and iritis. In the first it was due to swelling of the lens, in the others it probably was caused by exudation into the vitreous. It was only a symptom, disappearing with the disease causing it.

Dr. J. Green, of St. Louis, had first noticed myopia after iritis in his own case, as the inflammatory symptoms were subsiding. This was twenty years ago, and he had been on the lookout for myopia after iritis ever since. It is not uncommon.

EVENING SESSION

Hysterical Blindness in the Male.

Dr. W. O. Moore, of New York, reported three cases. The first was in a man who had shown various nervous symptoms for about two years. He claimed to have no light-perception in the left eye. It, however, appeared normal; and the placing of a prism, with its base up, before the good eye, caused vertical diplopia. He was assured of a speedy cure by electricity. The Faradac current was applied, and its strength suddenly increased, so as to cause a decided shock. After this he could see some. After a second application he could read 20-50, and, after the third, 20-20.

In the family history of the second case there was some insanity. He had used a mydriatic 18 months before, had become excited over its effects, and began wearing dark glasses, then shades over the eyes, and soon confined himself to a dark room. He was suffering from the effects of this confinement, and claimed to be entirely blind. He was etherized, and the ophthalmoscope showed the eyes to be normal. A free division of the outer canthus was done on each eye. On recovering from the ether, he was told that the cause of his blindness had been discovered and removed. The next day he

could walk about alone, and he quickly recovered full vision.

The third case was in a boy of fifteen, disappointed as to obtaining a prize in school. He soon began to complain of his eyes, and, when seen, gave a history of complete blindness of the right eye for one month. Appearance normal, diplopia with prisms. He was etherized, and the good eye bandaged. On recovering from the ether, he gave convincing proof of his ability to see with the other, and could soon read 20-20 with it. It is a mistake to dismiss patients of this kind with the statement that there is nothing the matter.

Dr. E. Jackson had seen a colored boy of twelve, who claimed to have only light-perception. He was cured by the use of a mydriatic, with a confident prognosis that his sight would return as the effect of the drug passed off.

Dr. S. D. Risley reported a case of photophobia which suddenly developed in a person suffering from aphonia, on being thrown with a person whose eyes were under a mydriatic. The aphonia disappeared as the photophobia appeared.

Tests for Partial Color-Blindness.

Dr. Charles A. Oliver, Philadelphia, read a paper on a description of a series of tests for the detection and determination of sub-normal color-perception (color-blindness), designed for use in railway service.

It is a well-known fact, he said, that many "color-blinds," especially those of medium grades, have the power of differentiation, even by daylight, of the most difficult colors when these are placed at the ordinary metre distance for wool selection, which is employed in the detection and determination of "color-blindness." Dr. Oliver has tried to overcome the dangers that might arise from this power in situations such as railways, marine and naval service, where the safety of lives and the protection of property are often solely dependent upon proper recognition of color at great distances, and frequently through the intervention of more or less translucent media. He seeks to combine two modifications of his method of color-selection by which the candidate is placed in the actual position of after-work and under circumstances exactly similar to those which exist during employment. The method is divided into three parts.

First.—The selection and registry of a definite number of loose wools from 23 pure and confusion-match skeins thrown upon a dead black surface at one metre distance.

Second.—The selection and registry of the same number of similar reflected colors under various intensities of diffuse daylight stimulus, placed at distances requisite for safety.

Third.—The selection and registry of transmitted colors under various intensities of artificial light stimulus, placed at distances requisite for safety.

In addition to the advantages shown to refer to the first test alone, the method has the following additional ones: (1) Much faster in time than any other method; (2) the selection of loose wools at a distance; (3) no necessity for an expert except in doubtful cases; (4) employment of the same character of signal for testing as is used in daily routine; (5) placing the eye during testing at a distance necessary for future safety; (6) bringing the eye during testing directly before the true condition of weather which will be experienced when the man is upon duty; (7) test and match colors all graduated in proportionate sizes.

Embolism of the Central Retinal Artery.

Dr. C. A. Oliver read the report of a case of this affection, ending in complete blindness of the eye affected. Dr. Mittendorf and Dr. Burnett referred to cases they had met with.

Second day, Thursday, July 19.

Double Congenital Absence of the Iris.

Dr. S. Theobald reported a case of double congenital irideremia in a boy eighteen months old. His mother, who brought him because of the red appearance of his pupils, stated that another of her children presented the same appearance. The point of chief interest was that the mother had a coloboma of the iris in each eye, in the right directly upward, and in the left upward and outward.

Dr. D. Webster, of New York, thought upward coloboma must be quite rare; he did not remember to have seen a case in which the deficiency of the iris occurred in that direction.

Dr. B. A. Randall said that there were a few cases on record of so-called coloboma inward and outward, but none extending upward. The case was unique.

Puncture of Detached Retina: Recovery.

Dr. T. Y. Sutphen, of Newark, reported a case. The detachment involved first the right eye, then the left also; and the area of detachment progressively increased until it was almost complete in both eyes. Rest in bed, diaphoretics, etc., had no effect; and, when the detachment had existed about six months, he introduced a needle through the sclerotic under the detached portion and punctured the retina. Considerable subretinal fluid escaped from the right, and very little from the left. The patient remained in bed and faithfully kept quiet for twenty-eight days after the operation. In both eyes the retina became completely replaced, but in the left the separation recurred, and a second operation gave no permanent improvement. In the right the cure seemed permanent; several months had elapsed, and he was now using the eye with vision of 15-20, with a glass correcting his moderate myopia.

Dr. E. Jackson had tried the operation in a detachment of some eighteen months' standing, where other means had failed. No improvement in the function or position of the retina resulted, but the patient had not remained in bed so long or faithfully as Dr. Sutphen's patient.

Dr. E. E. Holt, of Portland, had seen good recoveries under treatment by rest in bed and jaborandi. He had seen no improvement after puncture.

Dr. S. D. Risley had seen recurrence of a detachment from jumping off a moving street-car.

Glioma of the Retina.

Dr. F. P. Capron, of Providence, reported a case in a child of three and a half years. The growth, which protruded greatly from the orbit, was removed, but was recurring in the neighboring glands

Dr. J. F. Noyes, of Detroit, had once recognized the growth in the eyes of a child four years old, and advised enucleation. This was declined, and the child died within a year afterward, from extension into the orbit and neighboring parts.

Dr. W. F. Mittendorf could only recall having seen two cases of glioma; they seemed to be more frequent in some other localities. It would be well to have all cases studied with reference to their distribution and heredity.

Models and Sketches.

Dr. S. M. Burnett exhibited models made of wood and wire, illustrating the refraction of light by lenses.

Dr. B. A. Randall showed Sketches of Anomalous Outgrowths from the Optic Disk, and of Anomalous Distributions of the Retinal Veins.

Extraction of a Calcareous Lens, Giving Good Vision.

Dr. D. Webster reported the case. The left eye had been lost by injury, and was enucleated. The right had been the seat of iritic inflammation, and subjected to various operations. One attempt to extract the partly calcareous remains of the lens failed. A second attempt was successful, giving the patient vision equal 20-20.

The Numbering of Prisms.

Dr. E. Jackson explained his proposition to change the system of numbering prisms; and a committee consisting of Drs. Jackson, H. D. Noyes, and S. M. Burnett was appointed to consider the matter and report to the next meeting.

The meeting adjourned to meet in special session at the Arlington House, Washington, D. C., September 19, 1888.

Periscope.

Paralysis of the Fifth Nerve, Associated with Cataract.

At the meeting of the Ophthalmological Society of Great Britain, June 14, 1888, Dr. W. J. Collins showed a case of paralysis of all parts supplied by the sensory branches of the right fifth nerve. The muscles of mastication were unaffected. There was no history of syphilis and no cerebral symptoms. The patient had suffered from severe pain in the anæsthetic parts for eight months, and the sight of the right eye had failed. There had been no herpes, and no conjunctival or corneal affection whatever. There was diffuse opacity of the right lens; the left eye and side of face were normal, and vision was good. He considered that the lesion was located somewhere between the root of the nerve in the pons and the subdivision of the Gasserian ganglion. This case conflicted with the views of Snellen and others respecting trophic nerves. Here the lens, non-innervated, and protected from foreign irritants, suffered, while the highly-innervated and anæsthetic cornea retained its pellucidity, notwithstanding eight months' habitual exposure. Mr. T. Pridgin Teale mentioned a case of cataract, in which puncture of one lens was followed

by suppuration of the globe. The patient died shortly afterward with aphasia, due to cerebral hemorrhage, which was not entirely recent, but partly resulted from an accident many months previously. He suggested that the disastrous results to the eye might have been the result of the nervous lesion.—*British Med. Journal*, June 23, 1888.

Relief of Migranous Headache.

Dr. James Little, President of the King and Queen's College of Physicians in Ireland, in a communication published in the *Dublin Journal of Medical Science*, June, 1888, says that, though the typical form of migraine—consisting of the visual disturbance, hemicrania, and nausea—is not a very common affection, we frequently meet with persons suffering from headaches which seriously interfere with the occupations and comfort of life, and which appear to him to be of the same nature as the special neuralgia to which the term migraine is applied. These headaches occur at various intervals, sometimes only three or four times in the year, sometimes two or three times in a week. It is usually described as a dull disabling headache, and is first felt on awaking or immediately after getting up. Generally those who suffer from it say that they go to bed the previous night feeling especially well, but occasionally they have a warning of the approach of the attack on the previous afternoon. Sometimes the headache goes away after breakfast, but far more frequently the sufferer is unable to take breakfast, or finds that, whether he can take it or not, the headache increases. During the day he has distressing fits of retching, but usually is able to sleep when night comes, and the following morning he awakes merely weak. In a certain proportion of cases the headache is at first limited to one brow; and in these the invalid is less fortunate, for he generally finds that on awaking on the second day the pain has not gone, but has merely crossed over to the previously unaffected side of the head. The diagnosis of the nature of these attacks is very important. Those who suffer from them generally regard them as due to derangement of the digestive organs, and some of their advisers take the same view, and endeavor to avert the attacks by rigid care in diet and by medicines which act on the liver and digestive organs. Such measures, Dr. Little thinks, are very seldom of advantage, not infrequently rather the reverse; and, in speaking of these headaches as being allied to migraine, he desires to convey the idea that they are really neuralgic, and are to be postponed and relieved, when they come, by treatment directed to the nervous system.

Of the means which are useful in lessening the frequency of these headaches, he says the most efficacious are abundant exercise in the open air, a nourishing diet, sponging with hot water in the morning, followed by the cold douche over the shoulders and spine, and a very sparing use of tea. Among drugs the combination which has appeared to him to do most good is a pill containing:

℞ Sodii arseniat. . . . . gr. 1-12
Ext. cannabis Ind. . . . . gr. ⅙
Ext. belladonnæ . . . . . gr. ⅓
Zinci valerianat. . . . . gr. ii
M. Sig. Take after breakfast and dinner.

Up to October, 1885, he did not know of any treatment which had any distinct power of cutting short the attack when it came, or even mitigating its severity. Most patients found that if they refrained entirely from any attempt to take food, and were able to lie in a darkened room, they did all which was possible to lessen the intensity of their sufferings. Those who had on the previous evening a warning of their impending attack sometimes thought they kept it off by a full dose of bromide taken at bed-hour. Others found that a dessertspoonful of the granular citrate of caffein was beneficial, while some told me that lemon-juice or vinegar relieved the sickness and headache; but at this time it occurred to him to try salicylate of sodium, and, after more than two years' experience of its strikingly beneficial effect, he feels justified in commending it. He is in the habit of directing the patient, when he awakes with any feeling of headache, to take twenty grains of the salicylate in a wineglassful of water, made effervescent by the addition of a dessertspoonful of the granular citrate of caffein, and, if necessary, to take a second or even a third dose at intervals of two hours. The effervescing caffein makes the dose a very palatable one, which the salicylate alone is not, and probably renders it more useful; but that the good effect is not due to the caffein is proved by the fact that he has seen it relieve persons who had previously used the caffein alone without benefit. It does not, as far as he knows, lose its effect, as a patient of his, to whom he gave it more than two years ago, says that she finds it as valuable as when she first began its use. One woman informed him that she doubted the advantage of keeping off the attack, as she found that it did come at last, and was then far more

severe than ever. This, however, has been in Dr. Little's experience a solitary instance of the storing-up of the nerve-storm—a phenomenon which has been from time to time observed when epileptic seizures were postponed by the administration of the bromides—and its occasional occurrence does not lessen the propriety of keeping off the headaches when it can be done.

Dr. Little then reports the following illustrative cases:

"*Case 1.*—On November 25, 1885, Miss H., aged thirty, consulted me for attacks of pain in the left eye, and around, and to the outer side of, the eye. The pain was always felt on first awaking, and was accompanied by general headache and by nausea. She had pain in the region of the sigmoid flexure, and very confined bowels, and she had noticed that if she neglected taking aperient medicine the attacks were more severe. She also suffered from coldness of the hands and feet, but was otherwise in good health.

"I prescribed the pills to which I have already alluded, an aperient, consisting of equal parts of the liquid extract of cascara and syrup of ginger, and the salicylate of sodium and caffein. I never saw the lady again, as she does not live in Ireland; but six months afterward her mother consulted me, and told me that the salicylate and caffein had proved quite effective for cutting short the attacks.

"*Case 2.*—On March 20, 1886, Mrs. M. consulted me. She had suffered from headaches for about ten years; up to December, 1885, they had occurred about once every three weeks. Since that date, she had had one nearly every week, and they had been much more severe. She slept well; but, on awaking, felt shooting pains in the back of the head and tightness across the forehead, which ended in dull heavy pain all through the head, often accompanied with feeling of pins and needles in the right hand. She also suffered from feelings of distension after meals, an unpleasant taste in the mouth, and confined bowels. She had already tried the granular caffein, and had found it sometimes useful. I advised her to dine early and take more exercise, to keep her bowels open by a pill of calomel, aloes, and asafetida, which had many years before been ordered for her by Sir Dominic Corrigan, to take hydrochloric acid after dinner, and the salicylate and caffein when she awoke with headache.

"More than a year afterward, I heard from her that she had found the salicylate and caffein most effectual in keeping off her attacks.

"*Case 3.*—Last summer a married woman, aged fifty-eight, sought my advice on account of headaches, which had begun eight years previously, two years after the cessation of menstruation. At first she had the headache every three or four weeks; but of late the intervals had been only ten or twelve days. The evening preceding the attack she feels drowsy, and during the night often has nightmare. She awakes about five o'clock with throbbing pain in the vertex, and retching almost immediately begins, and continues violently and convulsively during the day, so that she cannot leave her bed—the pain in the vertex continuing all the time. About eight o'clock in the evening her sufferings begin to abate, and next morning she is as well as usual. Much pale urine is passed during the attack; her appetite is always poor; she eats little butcher's-meat, and has confined bowels. She suffers almost every night, more or less, from nightmare, and is constitutionally anxious and easily worried. This patient had consulted a London physician, who deservedly has a great reputation for his knowledge of maladies of this nature, without benefit, and had been long under the care of one of the most skillful Dublin physicians, at whose suggestion I saw her. I advised her to take pills of bromide of zinc and Indian hemp twice daily, and to use the salicylate and caffein when the attack began. The pills had no effect in keeping off the attacks; but the salicylate and caffein proved quite effectual in cutting short each attack, and had not lost their power after nine months."

Self-Mutilation of the Scrotum.

Dr. Alexander A. Leshtchinsky reports the following case in the *Russkaia Meditzina*, No. 6, 1888, p. 97: An intense aversion felt by the kind-hearted, peaceful, and industrious Russian peasantry toward the military service from century to century, furnishes a near and sufficient explanation of the fact that all over the vast empire there flourishes a numerous class of specialists — mostly retired *feldshers*, medical assistants—whose practical work consists in secretly maiming recruits in all possible ways affecting the qualification of the patient as an "unfit." The tale of Dr. Leshtchinsky may be taken as a typical illustration of what is daily done by the "surgeons" in question. The author was recently called to an athletic Lettonian peasant of twenty, by his brother, who frankly confessed that, about five days before,

the patient had been made "unfit" by a local *feldsher* in this way. The "surgeon" had taken the lad to a Russian bath, placed him on the *polok* or sweating-loft, and, after a good "steaming through" of the field of operation, pierced the patient's scrotum, through its whole thickness in an upward direction, by a big (saddler's) needle armed with a thread soaked in a caustic oily yellowish liniment; having drawn the needle out of the upper puncture, the operator had cut the thread with scissors, and withdrawn it from the lower punctures. At the time, the lad felt only a slight local burning; but on the next day there appeared a rapidly increasing, exceedingly painful swelling of the scrotum, with a vivid redness; on the third day a rigor followed, while pain and swelling became so great that the lad walked with difficulty. On the fourth day an abscess about the puncture made its appearance, bursting spontaneously and giving vent to a profuse blackish purulent discharge. When seen by the author on the fifth day, the patient lay on the floor with widely separated thighs, and was loudly groaning from an agonizing pain. His scrotum was found to present an intensely red, glossy, tense globe as large as the head of an infant of two or three months. Its lower integument, however, was covered with vesicles, erosions, and dark-blue sloughing spots, while on its posterior aspect, corresponding to the right testis, there was seen a large irregularly oval ulcer of the size of a florin, with uneven ragged edges and flat bottom lined with a grayish tallow-like coat. The right testis and epididymis were considerably enlarged and highly tender. Under the influence of an antiseptic dressing and ice, the youth recovered in about a fortnight. His purpose had been realized, the recruiting committee had rejected him as an "unfit" on the ground of an examination on the third day of his self-inflicted disease. —*Annals of Surgery*, July, 1888.

Posterior Spinal Sclerosis.

At the meeting of the Cincinnati Medical Society, June 5, 1888, Dr. W. H. DeWitt presented a case of posterior spinal sclerosis. The patient was a lithographer, aged 37, married, and having a family. So far as the use of alcohol was concerned, the man was temperate in his habits. He occasionally drank beer, but for several months past he had not done that. Since his seventeenth year he has been an inveterate smoker, but this too, and the use of tea and coffee, he abandoned some time ago. For the past five years he has complained of paroxysmal pains. For the past three years the pain has been circumscribed, located to the left of the lower dorsal region. The ataxia is only of recent development. The pain has been so severe at times that morphia was demanded for its relief. There was no disturbance of vision, but there was some difference in the size of the pupils. There was a difference, too, in the reflex response of the pupils to light, it being much more marked on the left side. The right one was very sluggish. There had been no visceral crises in this case. There was no trouble with the stomach or bowels, and none with the bladder. There was pain along the great sciatic nerve, and on the outside of the foot. He had difficulty in walking, especially at night. Walking up or down stairs was done with some difficulty. About five months ago he began to experience a numbness on the right side below the knee. The condition of the patient has improved under the use of the galvanic current and 1-6 grain of calabar bean before meals, and 1-25 grain of phosphorus after eating. The man has no history of syphilis. Sensibility of the soles of the feet, especially at the base of the large toe, is much less than normal. It is more marked in the centre of the sole. One of the interesting points in this case is the duration and locality of the pain. Its duration of five years is unusual, as is also the location of the pain in the lower dorsal region. Authors speak of abdominal and perineal pains.—*Cincinnati Lancet-Clinic*, June 30, 1888.

Some Cases of Habit Chorea and their Treatment.

In a paper on Some Cases of Habit Chorea and their Treatment, read before the Philadelphia County Medical Society, May 9, 1888, Dr. G. E. De Schweinitz said that it is well known that there are certain local choreas for which no definite cause can be assigned, and in which, as Dr. Wood puts it, the movements closely simulate purposive acts. A child suffering with this malady is brought for treatment because it has adopted some trick of gesture. An eye may be rapidly winked, or the eyeball rolled upward, or the brow wrinkled, or the facial muscles contorted, or, it may be, the shoulder is shrugged, or a forward movement of the head or jaw indulged in. At first, these movements are under the control of the will, but they gradually become more and more

obstinate and more and more aggravated, especially when attention is drawn to them, and sometimes the variety of the performances in a single day is truly remarkable. Dr. Weir Mitchell has given the name habit chorea to this affection.

After giving the histories of seven cases, with the results gained by the use of atropine or other mydriatic to full ciliary paralysis, and the correction of errors of refraction in the eye, Dr. De Schweinitz, in summing up, says that in three of them the habit spasm, as Gowers would say, had existed for a long time, and judicious internal medication and proper hygiene had failed to achieve the desired result; which result, however, was attained after the eyes had been thoroughly treated and corrected. In two others, the constitutional and the eye treatment were begun simultaneously, and the rapid improvement showed the value of this combination. In one instance, the eye examination and the correction of the anomalies of refraction were declined, and the habit still continues. In another, the wearing of the glasses was the only course pursued, and the result was most favorable. In all the cases, where errors of refraction existed, these were either hypermetropia or hypermetropic astigmatism; in two, the errors were two dioptres and more; in three, less than one dioptre, and in one the eyes were emmetropic. Dr. De Schweinitz calls attention to the fact that so low an error as half a dioptre may prove an exciting cause, the removal of which aids in restoring the patient to a normal tone. Case III, he says, is especially interesting, because here a general chorea disappeared, and in its place came a habit chorea. Exactly as Dr. Mitchell has observed, in a few instances, these cases lapse into well-pronounced chorea of the ordinary type. It is further useful to observe, he says, that the eyes in this case were emmetropic, but that, when the existing spasm of accommodation and phlyctenular conjunctivitis had disappeared under the use of the atropine, the patient made rapid strides along the road to recovery. He then speaks of the value of closely observing the condition of the conjunctiva, especially of the retro-tarsal folds, in this malady. Years ago, he says, the late Prof. Fr. Horner called attention to the fact that children, when first they attended school, were sometimes observed to be given to undue winking of the eyes, and that without the presence of strong light. As an accompaniment, there were often movements of the muscles of the face, arm, or leg. In these cases, the local cause was most often found to be some disorder of the conjunctiva, especially follicular catarrh, blepharitis, or an anomaly of refraction, usually hypermetropia. Indeed, in a few instances, the local condition was manifestly the exciting cause of a chorea minor. Treatment of the conjunctival catarrh and correction of the hypermetropia removed the difficulty. Dr. De Schweinitz thinks that not only may the local conjunctival disturbance and the refraction-errors exist, but there may be also imperfect equipoise of the eye-muscles. It is scarcely necessary to refer to this as a possible important factor. In recent times, much graver nervous disorders have been attributed to such insufficiencies of the ocular muscles, and, for their correction by surgical and other means, most brilliant results have been claimed.

Dr. De Schweinitz disclaims any intention to give an undue importance to these errors of refraction and inflammation of the conjunctiva as exciting agents in the causation of habit chorea. He does not forget that the large number of instances which may be directly traced to nasal disorders, to diseases of the pharynx; nor that other large class to which no adequate cause can be assigned. He only wishes to recall to the memory the value of searching for these among the other causes, and to emphasize the fact that, if the habit spasm especially affects the muscles of the face, particularly those around the eye, the following points deserve attention:

1. The condition of the refraction and the muscular balance should be carefully examined, and, if found abnormal, corrected.

2. The anomaly of refraction should be determined under complete ciliary paralysis, and the full, not a partial, correction ordered.

3. This correction should be employed in conjunction with proper internal medication and general hygiene, and not to the exclusion of these measures.

—Mrs. Wilhelmina Rhodes, an inmate of the Pennsylvania Hospital for the Insane, committed suicide by hanging, at the institution, July 27. It is said she was troubled with mental depression for years. One of the attendants is said to have seen her alive at five o'clock in the morning, and at half-past six o'clock the head nurse found Mrs. Rhodes suspended to a wardrobe by a sheet. She was already dead.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

INDICATIONS FOR THE REMOVAL OF THE UTERINE APPENDAGES.

There is no subject in the whole field of gynecology about which there has been a greater confusion of ideas than the diseases of the uterine appendages, and the indications for their removal. This has been largely the result of a faulty nomenclature. Pelvic peritonitis, recurrent or menstrual peritonitis, ovaritis, cellulitis, ovarian abscess, and pelvic abscess have long been recognized as morbid conditions But when, through the work of Tait, Hegar, and others, the etiological relation between disease of the tubes and the adjacent tissues became more generally recognized, and the terms salpingitis, peri-salpingitis, pyo-salpinx, tubo-ovarian abscess, etc., began to appear in current literature, these morbid conditions were not at once recognized under their new names. It is the etiology rather than the pathological anatomy of pelvic disease that has been advanced in the last ten years by operating surgeons.

The most radical change of opinion is that regarding the frequency of pelvic cellulitis. It has been conclusively shown that the "cellulitic masses," formerly so much discussed, are almost always enlarged tubes or ovaries, and that cellulitis and abscess of the pelvic cellular tissue, distinct from tubal and ovarian disease, are rare conditions.

The most frequent indication for removal of the uterine appendages is incurable inflammation. Cases of inflammation of the appendages may be conveniently divided into those in which pus is present, and those in which it is absent. When pus is present—either in the form of pyo-salpinx, purulent infiltration of the tube, or abscess of the ovary—it is generally accepted that the indication for removal is absolute. The surgical law that pus should be evacuated does not except pus in the pelvis. The ovaries and tubes are removed because they are pus-sacs. Until they are exsected, the woman's health is more or less destroyed, and she is constantly menaced by the danger of death from purulent peritonitis, set up by rupture of the sac and leakage of pus. Most operators favor the removal of both tubes and ovaries, even though the disease appears to be unilateral, especially in gonorrhœal cases. Where this cause can be excluded, a few operators leave the healthy tube and ovary. In cases of salpingitis and ovaritis, in which pus-formation has not occurred, the patient's life is seldom endangered. Here, operation is indicated only when the health is failing, or life is made miserable by suffering, in spite of well-directed conservative treatment. Cases of hydro-salpinx and hæmato-salpinx may be included in this class. Lawson Tait's name will ever be associated with the operation of removal of the appendages for inflammatory disease.

Before the successful application of elec-

tricity to the palliation and cure of uterine fibroids, and the arrest of metrorrhagia from other causes, the operation of removing the ovaries and tubes for the arrest of otherwise uncontrollable hemorrhage from the uterus seemed to have a brilliant future. The indication was based upon the well-known fact that uterine fibroids tend to undergo retrogressive changes after the natural menopause, and the object sought was to end menstrual life. Should electrical treatment yield the brilliant results which it promises, this field for the operation will be greatly restricted. It should not be forgotten, however, that fibroid tumors of the uterus are often associated with marked disease of the appendages. The ovaries were first removed for uterine fibromata by Trenholme and Hegar.

A less frequent indication for the removal of the ovaries is cystic degeneration and hæmatoma. Cystic degeneration, or hydrops folliculorum, is frequently associated with morbid conditions of the uterus, and with various reflex neuroses.

Ovarian hernia and absence or rudimentary development of the uterus, of such a character that the menstrual secretion is made impossible, although ovulation exists and gives rise to molimina and other disturbances, may call for the removal of the ovaries. In all cases, when convenient, the tubes also should be removed.

The final and least certain indication for removal of the uterine appendages is afforded by severe nervous and mental diseases, which stand in close etiological relation to the sexual functions. In these cases the bimanual examination usually affords no evidence of disease of the appendages, nor is this apparent on microscopical examination after removal. The operation should only be done when the indication is urgent, and after careful differential diagnosis, and the failure of conservative treatment properly carried out. It is with this class of cases that Battey's name is especially associated.

CONTAGION BY RESPIRATION.

The part borne in the communication of contagious diseases by respiration of the breath or cutaneous exhalations of diseased persons is by no means fully understood. There are those who are inclined to attribute an important *rôle* to this act, while others do not think it very important. An interesting contribution to the subject has been made by Cadéac and Malet in the *Lyon Médical*, No. 14, 1887, and an abstract of their report is contained in Virchow and Hirsch's *Jahresbericht*, vol. i, part 2, for 1888.

According to this abstract, Cadéac and Malet, by an ingenious series of experiments, demonstrated, as clearly as a negative can be demonstrated, that the prolonged and exclusive respiration of the breath of animals affected with splenic fever or sheep-pox will not communicate the disease to other animals. The emanations of portions of the bodies of animals dead of various diseases—such as erysipelas, splenic fever, tuberculosis, and septicæmia—proved equally ineffectual to produce the same diseases when conveyed directly into the lungs.

These results tend to confirm the opinion to which ordinary clinical observation might lead one—that breathing an infected atmosphere is not a very dangerous mode of infection. If it were, it would be hard to explain the immunity of nurses and physicians who are brought into such frequent and intimate relations with persons suffering with contagious diseases. Experience indicates that much of the fear felt by the laity in regard to the gaseous emanations of the sick is the result of preconceived notions, and is not warranted by any accurate observations.

This fact may serve to reassure those whose lot is hard enough in caring for persons affected with serious diseases without the addition of imaginary terrors, while it could not be strained by any sensible person to excuse the omission of any practicable measures to secure fresh and pure air for the lungs of both patients and attendants. There may be no great danger in the breath

or cutaneous emanations of a sick person, but they are certainly far from pleasant, and fresh air is a most important requisite for recovery from sickness and for escaping the risk of contracting disease.

LOCAL EFFECT OF LIME-WATER.

We have more than once of late called attention to the virtues of certain medicines and methods which have apparently been almost forgotten in the exciting and fascinating pursuit of new remedies, and whose quiet achievements have seemed to pale before the bold claims and glittering promises of the chemical and physiological laboratories.

These medicines and methods have been of that interesting class which illustrates the value of the empirical method, and the fact that the art of medicine still keeps far in advance of the science. Long before the *rationale* of the action of balsams upon wounded and inflamed surfaces was understood, men applied balsams successfully; and no doubt many a medicament now in successful use will wait long before its *modus operandi* will be understood.

But it is interesting when science begins to furnish an explanation of what art has been practicing, and it is gratifying to the human mind to think it knows why, as well as what, it does. A good example of this state of things is furnished by some recent discussions of the mode of action of lime-water, when used as a remedy for various anginas. Our readers know the reputation of lime-water as a solvent for false membranes, and they may have been puzzled at times to reconcile this reputation with its well-known astringent properties. In the *Berliner klinische Wochenschrift*, No. 18, 1888, Dr. E. Harnack gives a clear summary of what is now known in regard to the action of lime-water in dissolving the mucin which agglutinates the diverse elements of most false membranes, in combining with the fatty acids contained by all of them, so as to saponify them, and in rendering the mass easy to disintegrate by its mild astringent properties. Harnack is disposed to attach some importance to the liberation of carbonic acid from lime-water, in the presence of false membrane, and the deposit of fine particles of lime which mechanically interfere with the propagation and movement of micro-organisms. The latter notion is perhaps a trifle fanciful; but the rest of the explanation is as satisfactory in a scientific sense as it is gratifying to the complacency of those who like to regard medicine as a science as well as an art. To those who have learned to regard lime-water as by far the best, as well as the simplest, local application in diphtheria, it is pleasant to have an explanation of how it produces its grateful effects, and a scientific authorization for their empirical methods. But this mental gratification does not compare in importance with the value of a knowledge of the fact that lime-water is an admirable remedy in cases of diphtheria. Its local effect is most useful in cleansing and purifying the fauces, and its mode of application is the easiest imaginable. It requires no spray apparatus, no douching, and no effort at gargling. It is sufficient to have the patient slowly swallow a teaspoonful or more every hour, in order to get good results from its use. This fact is of the greatest importance in treating children, who are too often cruelly tortured in the attempt to make local applications to the throat. Lime-water can be given easily, and is taken readily by children; and there are, we believe, few cases of diphtheria which require a more energetic local treatment than the one just described. In fact, we think that an early clearing-out of the bowels with calomel—sometimes in massive doses—followed up after a short interval by the administration of lime-water, and the use of a suitable tonic and roborant regimen, constitutes a method which comes the nearest to being of universal applicability of any one with which we are familiar; and we think that the use of the lime-water is of more consequence than any other part of the treatment, except it be the preliminary purgation.

EPISTAXIS AND INTERSTITIAL NEPHRITIS.

The occurrence of grave hemorrhage from the nose is not very common, but it is by no means so infrequent that a serious inquiry as to its causation should be passed by without notice. In the *Gazette Hebdomadaire*, July 6, 1888, there is a communication by M. E. Gaucher, in which an attempt is made to show, on the strength of a single observation, that severe epistaxis may be due to interstitial nephritis. The communication is very interesting, and may supply a suggestion of great value in studying the conditions surrounding a case of severe and unprovoked epistaxis. Unfortunately, however, there are features connected with it which rob it of much of its supposed value.

In the first place, the case reported stands alone; in the second place, if the diagnosis was correct, the presence of interstitial nephritis in a person who suffered with dangerous hemorrhage from the nose may have been a mere coincidence. But the most serious defect in the report is found in the fact that it contains no evidence that the patient had interstitial nephritis except the statement that he had a considerable quantity of albumin in his urine. The absence of any statement in regard to a microscopical examination of the urine makes the assumption that interstitial nephritis was present wholly gratuitous. It is not unlikely that this assumption was correct; but it cannot be accepted on the evidence offered.

Notwithstanding this fact, the suggestion of M. Gaucher deserves attention; and it might throw useful light upon the subject of grave epistaxis if medical men made a habit of examining the urine carefully in all cases where it occurs without an obvious cause, and, if it were found that disease of the kidney was a regular concomitant of it, the treatment would not be limited—as it now is, in most cases—to efforts to control the bleeding by local applications, and to the time when the hemorrhage takes place.

We commend this matter to the attention of our readers who may have opportunity to confirm or correct the opinion expressed by our French colleague.

CARBOLIC ACID IN SMALL-POX.

The experience of Dr. A. Montefuso in a recent epidemic of small-pox in Naples indicates that carbolic acid is capable of yielding excellent results in the treatment of this disease. Its use as an ointment did not prove especially beneficial, but, according to the *Bulletin gén. de Thérapeutique*, April 15, 1888, doses of from fifteen to thirty grains (daily?) in about eight fluid ounces of water, for adults, led to a decided and usually permanent fall in temperature, with diminution in the frequency of the pulse and improvement in its force.

Montefuso came to the conclusion, from his experience, that carbolic acid is the only remedy which has a real influence upon the eruption in variola. He found it to limit the extent and the duration of the eruption, although he does not claim for it an abortive action. When used at the beginning of an attack, the pocks are often seen to become wrinkled and to dry up in a few days, without involvement of the subcutaneous connective tissue. When suppuration has already begun, the effect on the eruption is not so obvious, but the effect on the constitutional condition is manifest.

Montefuso did not observe any disturbance of the gastro-intestinal canal, or—except in one case—of the genito-urinary apparatus, from the doses he used and recommends. The only contra-indication to the administration of carbolic acid in small-pox which he mentions is marked nervous manifestations.

If the observations just cited have been carefully made, they certainly justify testing the value of this remedy further. It is not the first time it has been proposed; but Montefuso's experience is one of the most encouraging with which we are acquainted. It will not be forgotten that the treatment of small-pox nowadays is largely symp-

tomatic, and that the fatality of the disease under any treatment is much less than it was formerly; but any remedy which has a decided influence upon the fever and the development of the eruption would be a valuable addition to the physician's armamentarium.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE LANGUAGE OF MEDICINE. By F. R. Campbell, A.M., M.D., Professor of Materia Medica and Therapeutics, Medical Department of Niagara University. Octavo, pp. viii, 318. New York: D. Appleton & Co., 1888. Price, $3.00.

The object of this book is to provide the medical student with the means of acquiring a correct vocabulary of medical science, and is intended for those who have not had the advantage of a classical education. It contains a sort of epitome of Latin and Greek grammar, with exercises intended to familiarize the student with the subject. We are of those who believe that the best preparation for the study of medicine would include a study of the classics, and are disposed to regret that any student should require a book of this kind. As, however, there are many such students, we very warmly recommend to them this book, which is admirably conceived and admirably executed. One of its merits, we think, is that it is likely, if properly appreciated, to give the student a taste for classical education, which may happily lead him to more profound studies.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

A New Method in the Treatment of the Vegetable Parasitic Diseases of the Skin. By Henry J. Reynolds, M.D., Chicago. Read before the Section on Dermatology, Ninth Inter. Med. Congress, Washington, D. C. 8 pp.

Water. Its Impurities, gathered from the Air and Earth. By C. W. Moore, M.D., San Francisco. From the *Pacific Record of Medicine and Surgery*, March 15, 1888. 79 pp.

—Dr. Reynolds proposes the application of parasiticides to the skin, with the favoring action of the electric current. It is well known that the electric current facilitates the passage through the skin of absorbable medicaments, and Dr. Reynolds applied this principle in the treatment of a case of favus and two cases of tinea tonsurans with entire success. His experience has since been confirmed by Drs. Charon and Gevaert, of Brussels, who used corrosive sublimate in solution—three to five parts per thousand—as the parasiticide. Dr. Reynolds does not state what he used, but gives plain directions as to the way in which the electricity is to be employed. His paper must prove of interest, for anything which suggests a way of cure for stubborn skin-diseases must be interesting. It may be remarked that the method he suggests might prove useful in scabies, as well as against vegetable parasites.

—Dr. Moore has gathered into this pamphlet a number of facts relating to the impurities contained in water, and especially the drinking-water of San Francisco. Incidentally, he discusses the nature of bacteria and the origin of life. His views are in some respects singular, as he seems to believe in spontaneous generation. He, however, makes a warm plea for securing the highest degree of purity possible in drinking-water, and advocates filtration and a special apparatus for this purpose.

Literary Notes.

La Médecine Hypodermique is the name of a journal to be published in Paris, of which the first number has just reached us. It is dated July 1, 1888. Its price is four francs a year, and, after January, 1889, it is to be issued monthly. Persons subscribing now are to receive *gratis* the numbers until January 1. The first number contains 13 pages devoted to medical science, eight of which are devoted to hypodermic medication.

Ipecacuanha Spray in Throat Cough.

Dr. Wm. Ellery Briggs writes to the *Sacramento Medical Times*, July, 1888, that, since reading of Dr. Morrell's use of ipecacuanha spray, he has used it in five cases, all of which improved in a gratifying manner, so that he with much confidence recommends it to the profession. The first case in which he used it was one of catarrhal laryngitis, in a patient 26 years of age, with phthisical family history. After the second inhalation of a drachm and a half of ipecacuanha wine and an equal quantity of water, his cough was much relieved and the expectoration diminished; and after the tenth daily administration, he considered himself entirely well, and went to the country to continue work on a ranch. The vocal cords and mucous membrane of the larynx were less congested after the third application, and appeared quite healthy when he discontinued treatment. When first sent to Dr. Briggs for treatment, his paroxysms of coughing were violent and almost continuous. This condition had existed for more than a week. A second case was similar in its effects, in a young man of 30, who had been suffering for several months, and had been under Dr. Briggs's treatment for the laryngeal affection for three weeks previous to the use of this remedy, without very marked improvement. The three remaining cases, he says, present no special point of interest. It may be administered with a steam atomizer or a hand-spray. If used by the latter method, the solution should be warmed previous to its inhalation.

CORRESPONDENCE.

Picric Acid Test for Sugar.

TO THE EDITOR.

Sir: Will you please publish in your next issue the picric acid test for diabetic urine and oblige A SUBSCRIBER.

Chillicothe, Ohio,
July 28, 1888.

[To a fluid-drachm of the urine, add forty minims of a saturated solution of picric acid, and then half a drachm of liquor potassæ. Boil the mixture, and, if sugar is present, a dark mahogany-red color will be produced, due to the reduction of picric acid to picramic acid. EDITOR REPORTER.]

NOTES AND COMMENTS.

Summer Diarrhœa or Entero-Colitis.

Dr. Louis Starr, Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania, writes as follows in the *Medical Standard*, July, 1888:

Therapeutic measures often fail in relieving this condition when they are uncombined with rigid enforcement of the general rules of health. The main hygienic features to receive attention are the following: Fresh air must be secured by taking the child to a public square in the cool of the morning and evening, or, better still, by a morning or evening trip on the water. The heat of the day must be spent in as cool a room as can be had. Coddling is to be discouraged, as many a stout mother has hastened her infant's death by too fond and constant nursing in the arms. The clothing must be as thin as possible, provided that woolen is always worn next to the skin. Twice or three times a day in very hot weather, the whole surface of the body must be sponged with water at a temperature of 80° F. and dried with gentle rubbing. The addition of rock salt renders these baths more bracing. Full warm baths must supplant the cold sponging if there is much prostration.

The diet is to be most carefully regulated as to quality, quantity, and intervals of administration. Sound cow's milk must form the basis of the food in bottle-fed babies, and peptogenic powder is a very useful addition to it.

Medicinal treatment varies with the case. Should the patient be seen early in the attack, it is initiated by a laxative. A teaspoonful of castor oil with ten drops of paregoric, or the same quantity of spiced syrup of rhubarb, is sufficient for an infant of one year. Afterward, while the stools are yellow, homogeneous, and not very frequent, alkalies and astringents are employed:

℞ Sodii bicarb. . . . . gr. xxxvi
Syr. rhei aromat. . . . . f℥ iv
Mist. cretæ . . . . . q. s. ad f℥ iii

M. S. One teaspoonful every two hours for a child one year old.

When the stools are frequent, green, and acid in reaction, the following may be employed:

℞ Syr. rhei aromat. . . . . f℥ iv
Bismuth. subcarb. . . . . ℥ ii
Syrupi acaciæ . . . . . f℥ iv
Misturæ cretæ . . . . . q. s. ad f℥ iii

M. Sig. f℥ i every two hours. At the same time the abdomen is to be reddened two or three times a day with a weak mustard draught—one part of mustard to five of flour.

If the evacuations are liquid and contain whitish or greenish flakes, and the above treatment fails after a fair trial, good results often follow a short mercurial course, thus:

℞ Pulv. ipecac. comp. . . . . gr. ii
Hydrarg. chlor. mit. . . . . gr. ss
Cretæ preparat. . . . . gr. xxxvi

M. ut ft. chart No. xii. S. One powder every two hours for twenty-four or forty-eight hours, or until the stools become yellow and homogeneous.

Should the stools be frequent and serous, more powerful astringents are used, as aromatic sulphuric acid, silver nitrate, or zinc oxide.

When the stomach is very irritable, rectal injections are resorted to, the drugs used being tincture of opium, nitrate of silver, and ipecacuanha. Ipecacuanha is chosen where there is much tenesmus with the discharge of blood and mucus. It may be administered as follows:

℞ Ext. ipecac. fl. . . . . m xii
Tr. opii deod. . . . . m viii
Mucilag. acaciæ . . . . . q. s. ad f℥ i

M. S. Inject one tablespoonful every four hours.

Stimulants—wine of pepsin, brandy, or whiskey—are given in all infantile cases where there is prostration.

In cases of recovery, the diet and hygiene must be carefully watched until all danger of a relapse has passed; the astringents are gradually dropped, and digestants and tonics ordered.

The antiseptic treatment recommended by L. Emmet Holt, I have lately tried with good results. It embraces the careful attention to regimen already alluded to, preliminary evacuation of the bowels with castor oil, and the administration of naphthaline or

of sodium salicylate. Naphthaline is usually ordered as in the following prescription:

℞ Naphthaline,
Ground coffee . . . . . āā gr. vi
Sugar of milk . . . . . gr. xxiv
M. ut ft. chart No. xii.
S. One powder every two hours.

In conclusion, it may be well to draw attention to the fact that the key-note of successful treatment seems to be the maintenance of constant circulation in the contents of the intestinal tract. The object of this is to sweep irritating fecal matter or secretions away from the intestinal mucous membrane and give the latter an opportunity to recover from the catarrhal inflammation affecting it. Castor oil and calomel are the best drugs to accomplish this, and small frequently repeated doses are to be preferred to single large ones, active purgation being undesirable. With bowels so swept, a bland unfermenting diet, and attention to the health-rules already mentioned, every aid is furnished to secure the successful action of such remedies as bismuth subcarbonate, naphthaline, and sodium salicylate.

On the other hand, should opium be used to lock the bowels, one great factor in the causation of the disease is fortified in its position, and an increase in the degree of inflammation almost invariably results. The opium used in the foregoing prescriptions is only intended to prevent griping or to secure retention in the case of the injection, not for the purpose of checking peristaltic action of the intestine

In some cases, especially when there is irritability of the stomach, milk, in no matter what form or how prepared, seems to keep up the disease. Under these circumstances, my plan is to order one or two teaspoonfuls of raw beef-juice every two hours, according to the age. This diet may be continued for several days until the vomiting stops and the movements improve in character, when a milk diet may be resumed.

One must not forget that a change of climate is a most efficient method of treatment, especially when the seaside is the objective point.

Poisoning with Chloroform.

Dr. Robert Hoffman, in reporting a case of chloroform-poisoning in the *Maryland Med. Journal*, June 16, 1888, says that he was hastily summoned one night to attend a man 50 years old, who 15 minutes before had swallowed a large tablespoonful of pure chloroform, which he had mistaken for a solution of iodide of potassium. The patient was thoroughly narcotized; there was no reaction of pupils; the pulse was small and frequent; respiration deep and very slow; face and extremities cold, and a strong odor of chloroform was perceptible in the man's breath. The patient's friends said that he cried out immediately after swallowing the chloroform, then fell and lost consciousness. Subsequently the patient told Dr. Hoffman that as he swallowed the medicine there was an intense burning in his throat, which is all he remembers.

Dr. Hoffman had all the doors and windows immediately opened to clear the room of the chloroform vapor, and then resorted to the stomach-pump, experiencing no difficulty whatever in introducing the tube, as there was complete relaxation of the muscles. The stomach was emptied of its contents and then washed out several times with warm milk, all of which gave forth an intense odor of chloroform. The patient after this, however, showed not the least sign of consciousness, but lay in profound coma, with reflexes entirely absent, and pulse thready. Artificial respiration was then resorted to, which succeeded after long and patient trial in causing the patient to open his eyes for a moment, but he again relapsed into his former condition. The artificial respiration was continued, supplemented with hypodermic injections of strychnine; after a short time, the patient again opened his eyes and attempted to speak. He then gradually recovered, and in a few days was entirely well.

Cystotomy in Hypertrophy of the Prostate.

M. Berger has recently read a paper before the Société de Chirurgie of Paris, on cystotomy above the pubes in cases of hypertrophy of the prostate. A man who had dysuria from an enlarged prostate was catheterized, but the surgeon who attended him made a false passage, and all further attempts to pass the catheter failed. The bladder was then cut down upon in the suprapubic region, with a view of passing the sound from the bladder. The operation succeeded, but the man was unable to support the fixed catheter, and a permanent fistula had to be made through the primary incision, and a special instrument placed *in situ*. Thompson recommends perforating the bladder through the prostate with a large trocar, but M. Berger preferred the operation just described, as there was less risk of extravasation of urine. —*Medical Press and Circular*, June 27, 1888.

Clinical Value of Sulphonal.

Dr. Julius Schwalbe, after a careful analysis of the effect of sulphonal in fifty observations (*Deutsche med. Wochenschrift*, June 21, 1888), concludes that, in its pure form, it is an agreeable agent to use on account of its freedom from odor and taste; that it acts as an hypnotic in cases of "nervous" sleeplessness, in doses of 15 or 30 grains, with very acceptable rapidity. In insomnia resulting from direct organic disturbance, occurring in a disease of short duration, its action is more or less uncertain.

It has no effect upon temperature, pulse, or respiration, and for this reason, as well as on account of the properties just mentioned, it is to be preferred to morphine and chloral in febrile diseases, and in all affections in which weakness of the heart is to be feared. It should be employed especially in children. The subjective symptoms accompanying and following its employment are not of a kind to contra-indicate its use.

Codeine for Abdominal Pain.

Dr. T Lander Brunton, in a communication in the *British Med. Journal*, June 9, 1888, on the use of codeine to relieve pain in abdominal disease, says that the results which he has obtained from the administration of codeine have satisfied him that it has a powerful action in allaying abdominal pain, and that it can be pushed to a much greater extent than morphine without causing drowsiness or interfering with the respiration or with the action of the bowels. It is, therefore, he says, specially indicated in such a case as Dr. Philpot's, in which the dilated heart and consolidated lung tended to make one afraid of morphine. Codeine is also specially indicated in a case like Dr. Pardington's, in which one wished to relieve the pain without interfering with the action of the bowels. On the other hand, in cases where there has been much diarrhœa, as in some cases of malignant disease of the colon or rectum, the absence of any tendency to lessen peristaltic movement is rather a disadvantage to codeine as compared with morphine or opium.

He has found that, in cases of long-continued enteralgia without organic disease, it has continued to relieve pain for months together, without the dose being increased beyond one grain three times a day, and he found the same to be the case where the presence of a tumor, in addition to other symptoms, had led to the diagnosis of malignant disease. It is interesting, he says, to follow the vicissitudes of a drug, and to notice how its use extends or diminishes until at last it finds its right place and maintains it. Thus digitalis, while mentioned in the London *Pharmacopœia* of 1721, was excluded from that of 1746. It again appeared in 1788, and since then it has held its place. Possibly codeine, after falling into almost complete disuse as an analgesic for many years, may again regain a more or less important place among the remedies which enable us to relieve pain.

Blue Spots in Typhoid Fever.

Dr. William Osler, in an editorial in the *Canada Med. and Surg. Journal*, June, 1888, says: "With the rose-colored rash in typhoid fever or occurring alone, there are sometimes to be seen bluish spots on the skin of the abdomen, back, and thighs, ranging in size from two to eight lines in diameter, and often arranged in groups. They were called *taches bleuâtres* by the French, and by this name have passed into literature, though the term peliomata has also been applied to them. Murchison gives a good description of them in his work on fevers (for good illustration, see his Plate V), and agrees with Jenner that they are usually seen in light cases. Though not very common, I have usually each session an opportunity to demonstrate them, and my attention has recently been directed to the subject by their occurrence in three cases in succession, all very severe.

"In my experience, they occur indifferently in severe and mild cases. The spots are not elevated, but in certain light may appear, as Forget notes, depressed. They do not occupy the same layers of the skin as the typhoid rash, but are rather subcutaneous, as the pale dermis may be seen above them. Firm pressure causes them to disappear, and they fade after death. Murchison and Jenner state that they persist after pressure; but certainly, in the cases in which I have tested this point, the lividity could usually be removed.

"The condition is not peculiar to typhoid, but occurs in relapsing typhus and simple fevers. I have never seen it except in association with the febrile state. I believe it to be a vaso-motor disturbance, inducing local areas of congestion in the subcutaneous tissue. Duquet and other French writers have expressed the opinion that they are caused by pediculi pubis, not by the punctures, but by the saliva extruded on to the skin. Certainly, the 'blue spots' occur in cases in which no pediculi can be found, and it is curious that they should come out only in conditions of fever."

Meddlesome Midwifery.

In the *Archiv für Gynäkologie*, Band xxx, Heft iii, Credé, of Leipzig, expresses his decided convictions in favor of non-meddlesome midwifery, and bases his belief on the critical study of 8,000 puerperal women. He expresses the view that what is needed is a rule of practice under all circumstances the safest in hospitals or dwellings. He cites 2,355 cases with 0.3 per cent. mortality from sepsis. He lays stress upon preventing loss of blood as far as possible, on thorough disinfection of all which has to do with the patient, and on thorough antisepsis when interference is demanded. Regarding vaginal and intra-uterine douches, he remarks: "The statement made in so many case-histories that the patient's condition became worse '*in spite of*' antiseptic vaginal and intra-uterine injections diligently used would be more correctly rendered in many cases if the word '*because*' were substituted for 'in spite of.'" He reports a septic mortality of 0.6 per cent. in the Poliklinik, where the conditions are essentially those of private practice, and he indicates this as what, in our present knowledge, might be expected in private practice.—*Medical Press and Circular*, June 20, 1888.

Menstruation in a Child Three Years Old.

Dr. H. Kornfeld describes in No. 19 of the *Centralblatt für Gynäkologie* a case of menstruation in a child three years old. The child, which was addicted to onanism, had on April 5 a hemorrhage from the genitalia, which diminished at noon, and had disappeared the next morning. An injury—an abraded spot or any other source of the bleeding—was certainly not present. Bleeding recurred regularly at the beginning of May, June, July, at precisely the very time at which the mother menstruated.—*Wiener med. Presse*, June 17, 1888.

Treatment of Chronic Diarrhœa with Talc.

The Paris correspondent of the *N. Y. Medical Journal*, July 7, 1888, says: Dr. Debove has something new to propose in the treatment of chronic forms of diarrhœa. He says: "I have found the means used for the treatment of diarrhœa to be just as numerous as they are insufficient, and I concluded it would be well to attempt to stuff the intestines with some inert powder that would not be attacked by the intestinal juices." He settled on talc, which is a silicate of magnesium. This was given in doses of from six to eighteen ounces a day. It is finely pulverized and soft, and given in portions of six ounces to a quart of milk, great care being taken to add the old formula, "To be well shaken before taken." The amount of six ounces is usually enough to obtain a complete success in phthisical patients who get diarrhœa. It is interesting to note that many of these patients could not tolerate the milk treatment, or cod-liver oil, as they caused diarrhœa, but that after the administration of talc they got on very well, both with milk and with the oil, some of them taking as much as a pound of oil in twenty-four hours afterward, when they could not stand a moderate dose before without developing diarrhœa. The talc is a very light powder, and is eliminated in twenty-four hours, when the stools will be found quite white. It does not remain stationary in the bowels, but causes constipation, which, however, is not to be feared in such cases as M. Debove used it in, as the diarrhœa was of organic cause and was almost certain to return, kept up as it was by intestinal ulcerations. The use of talc was continued for some time in many of the cases, but it has not yet been tried in children, nor in diarrhœa of hot climates, nor in dysentery.

Camphoric Acid.

In the Berlin Medical Society Dr. Reichert recently read a paper on the local application of camphoric acid in various acute and chronic diseases of the nose, mouth, and upper portions of the alimentary canal. The acid has been known for a long time, and is produced by boiling camphor with nitric acid. It occurs in colorless crystals slightly acid and bitter to taste, soluble to the extent of nine-tenths per cent. in cold water, and easily soluble in alcohol and ether. For application, the author employed a solution of one or more per cent., to which sufficient spirit is added to make it clear. For use as a gargle, a solution containing from one-half to one per cent. was found effective, while from one to two per cent. was dissolved for application as a spray, and two-tenths part in a hundred as a nasal douche. A mixture of one part of camphoric acid and nine parts of boracic acid was employed as a powder for dusting affected surfaces. Reichert commends the action of the remedy as a fit subject for further investigation.—*Chemist and Druggist*, June 30, 1888.

New Way of Preserving the Dead.

The Philadelphia *Ledger*, July 26, says: "A Pittsburg physician, named Cooper, has just applied for a patent on a process to preserve human bodies by compression. By a curious combination of steel presses and hot rollers, he excludes all the moisture and reduces a full-grown body to a very small size, 12 by 15 inches, rendering it as hard and imperishable as marble. He has made several experiments with perfect success. The doctor and others who have investigated the process think it will supersede cremation, as bodies thus preserved are not only not offensive, but can be made to assume various ornamental shapes and be kept in the parlor or elsewhere as constant reminders of the departed. The doctor has on his centre-table the remains of a child pressed into the form of a cross. It resembles the purest marble, is highly ornamental, and is perfectly odorless. The inventor proposes to place a large number of specimens on exhibition in a few days. A company will be formed to push the invention."

Abdominal Abscess Following Enteric Fever.

At the meeting of the Nottingham Medico-Chirurgical Society, May 18, 1888, Dr. Michie read notes of a case of abdominal abscess following enteric fever and treated by abdominal section and drainage. The patient complained of pain and tenderness a little to the left of and below the umbilicus during the fourth week of enteric fever. Toward the end of the seventh week there appeared a hard and tender lump in the same situation; the patient had shiverings and night-sweats. At the end of the tenth week Dr. Michie saw the case in consultation with Dr. Brown Sim. At that time the swelling was about twice the size of a cocoa-nut, hard, slightly tender, movable; there was no discoloration of the skin. No fluctuation could be made out; there was nothing unusual in the pelvis, temperature 100° F., pulse slightly accelerated. The diagnosis was: Abdominal abscess having its origin in a suppurating gland of the mesentery. On February 1 abdominal section was performed, the abscess opened and washed out with plain warm water, and a large rubber drainage-tube inserted. The patient was dismissed on the twenty-first day after operation, all discharge having ceased and the wound healed. Dr. Michie attributed the speedy progress of the case to (1) the equable intra-abdominal pressure, (2) the large-sized drainage-tube, (3) the absence of any washing or syringing out of the cavity after the first time. He deprecated this practice in the treatment of abscesses or wounds generally.—*British Medical Journal*, June 30, 1888.

Surgical Soap.

In the *Revue Médicale de la Suisse Romande*, No. 5, 1888, page 285, Professor Auguste Reverdin, of Geneva, speaks highly of a "surgical soap" prepared after the following formula:

℞	Oil of sweet almonds	72 parts
	Caustic soda	24 "
	Caustic potash	12 "
	Sulpho-carbolate of zinc	2 "
	Essential oil of roses	9.5 "

The preparation consists in slowly adding to and carefully mixing with the almond oil the lyes and the sulpho-carbolate, part by part, until an intimate and homogeneous mixture is obtained. The latter is kept for several days at 68° F. The mass, which gradually acquires the consistence of soft paste, is then divided into any number of portions that may be desired; these are placed in suitable molds, where they are kept till they are completely solidified. Professor Reverdin has been using this antiseptic soap since the summer of 1887, when he visited Professor Bottini's clinic at Milan, where it is extensively employed for various purposes. The soap is said to possess wonderful cleansing as well as antiseptic properties, and it does not irritate the skin, however sensitive or irritable it may be. Moreover, as the soap contains an excessive proportion of fatty substances, it does not dry the skin. The presence of potash makes the soap by far more active comparatively than a pure sodic soap, since, as Dr. Unna has proved, potash has a more energetic solvent action on the horny layer of the cuticle than soda. Professor Reverdin recommends this soap not only for general use in hospital and private practice, but also for washing the hands in dissecting-rooms and everywhere where the hands come in contact with decomposing substances. Further, he urges that barbers should universally adopt this disinfecting soap for their purposes, and thus protect their customers from various infectious diseases, to which they are exposed in their shops. Dr. Reverdin has also obtained good results from this soap in various cutaneous affections. Finally, it is a very pleasant toilet-soap, as he himself and many of his patients and friends have found.—*British Med. Journal*, June 30, 1888.

Listerine.

A compound has recently been introduced under this name as a surgical dressing, and has attained considerable popularity in America. According to *Fortschritt* the following formula gives a preparation closely resembling it:

Benzoic acid, Borax	āā 2 drachms
Boric acid	4 "
Thymol	¾ "
Eucalyptol	10 drops
Oil of wintergreen	10 "
Oil of peppermint	6 "
Oil of thyme	2 "
Rectified spirit	5¾ fl. oz.
Water to make	31 "

—*Chemist and Druggist*, June 30, 1888.

Surgery Under Difficulties.

The daily newspapers of July 10 contained an account of the bursting of a boiler in a mill at Allentown, Pa., by which a number of persons were killed and injured. Among the latter was a man whose body was pinned to the floor by a heavy mass of iron, so that it was necessary, in order to free him, to cut off his foot and the lower part of his leg. One of the physicians who were summoned to the assistance of the injured performed the difficult operation successfully, so far as the operation was concerned, although the man had suffered such internal injuries as make his recovery very improbable.

Transplantation of Skin.

At the meeting of the Cincinnati Medical Society, June 5, 1888, Dr. C. R. Holmes presented a case showing an excellent result in transplantation of skin. The patient was a young man, who showed upon his forehead and side of his face the scars which resulted from injuries, with subsequent ulceration and necrosis. The injuries occurred when he was eight and nine years of age. He had applied for relief from an ectropion of the right lower lid, one of the results of this ulceration. The operation was performed May 16. Preliminary to the operation the upper and lower eyelids were united at their outer third by three stitches. These stitches were to be allowed to remain for three months. In performing the operation he made an incision and dissected up the loose tissue, when he found that there was little, if anything, covering the bone. The space was filled with a transplantation from the arm. The doctor made a pattern of the part to be supplied, and, laying this upon the arm, cut a piece of skin away of the same shape, but he allowed about 75 per cent. outside of the pattern. This was afterward found to be a little too large, and about one-sixteenth of an inch was trimmed away. The size of the transplantation was about two inches one way by one the other. Warm moist applications were made to the part for ten hours. Afterward warm dry heat was applied for sixty hours longer. Not until three days ago was there any sign of the loosening of the horny layer of the skin.—*Cincinnati Lancet-Clinic*, June 30, 1888.

Mills School for Male Nurses.

On June 28, Mr. D. O. Mills formally transferred to the Board of Public Charities and Correction of New York a building erected at his expense and designed to accommodate fifty pupils of the training school for male nurses, in connection with Bellevue Hospital. The building is situated on the hospital grounds, and will serve in addition for the pathological museum of the hospital.

NEWS.

—Dr. S. B. Kello, of Ivor, Virginia, died July 10. He was graduated from the University of Pennsylvania in 1841.

—There were sixteen deaths from yellow fever and one from small-pox at Havana, Cuba, for the week ended July 14, 1888.

—Prince Louis Ferdinand, of Bavaria, has completed his studies, and has received a diploma qualifying him to practice as a physician.

—The number of cases of yellow fever at Plant City and Manatee, Florida, is diminishing. There have been no new cases for several days.

—The new Marine Biological Laboratory at Wood's Holl, Mass., was formally opened July 17. Dr. C. O. Whitman is the Director of the Laboratory.

—Dr. Hermann Knapp has been appointed Professor of Ophthalmology in the College of Physicians and Surgeons, New York, succeeding the late Dr. C. R. Agnew.

—Dr. G. B. Johnston has resigned the Professorship of Anatomy in the Medical College of Virginia, and Dr. Louis C. Bosher has been elected to fill the vacancy.

—A second Chair of Anatomy is to be established at the University of Jena, to which it is expected that Dr. C. Bardeleben,

Prosector and Professor Extraordinary, will be appointed.

—Dr. H. Fritsch, Professor of Midwifery and Gynecology at Breslau, has been invited to fill the same chair at the University of Würzburg, made vacant by the death of Scanzoni.

—Dr. Stephen G. De La Mater, of Duanesburgh, New York, died June 23. He was graduated from the Albany Medical College in 1842, and at the time of his death was the only surviving member of that class.

—The sanitary inspector of Santiago de Cuba, says the *Weekly Abstract of Sanitary Reports*, reports, for the week ended July 14, ten cases of yellow fever and nine deaths at the military hospital. The cases are of soldiers newly arrived from Spain.

—Dr. Frederick C. Perpente, of Philadelphia, who is charged with criminal malpractice which resulted in the death of Andora Troxell on July 17, was found on Thursday night in a swamp near Bayhead, Ocean County, New Jersey, and was brought to the city July 28.

—Mrs. L. R Mosier, an "electropathic physician," was held in $2000 bail at Fitchburg, Massachusetts, July 29, for causing the death of Miss Nellie Shea, by criminal malpractice. The arrest was the result of a sworn statement of the dying girl, accusing Mrs. Mosier.

—A public meeting will shortly be held in Paris to protest against the stringent police measures regarding stray dogs. These regulations, which absolutely prohibit any dog to be in the streets unless led, were instituted chiefly upon the recommendation of M. Pasteur, against whom a certain portion of the French press is carrying on a violent campaign.

HUMOR.

"What becomes of the old moons, pa?" "The old moons, my son? Why, they die of newmonia, to be sure."—*Lynn Item.*

A man recently undertook to ascertain the age of a shark by examining his teeth. The next morning the papers gave the man's age to the very day.—*Puck.*

"Darringer, have you a half-dollar that you don't want?" "Why, certainly. Here it is." The next day: "Say, Darringer, that half-dollar you gave me was a counterfeit." "Yes, Bromley. You asked me if I had a half-dollar that I didn't want."

Old Gentleman: "Strange! I don't see a grave of a person as old as I am." His daughter: "Why, of course not, father; you must remember this is a comparatively new graveyard."—*Life.*

It does not require anything extraordinary in the way of intellect to shoe a horse, but there is a fortune in store for the man who can shoo a fly so that the little pest will stay shod.—*Harper's Bazar.*

A Correct Diagnosis.—Young physician (inspecting citizen on the floor at the police-station)—"This man's condition is not due to drink. He has been drugged." Officer McGinnis—"You're right. I drug him all the way from Casey's saloon, two blocks down the street."—*Life.*

A Narrow Escape.—Mérimée, referring to M. Viennet, of the French Academy, observed: "We must not speak ill of his tragedies. At the siege of Leipsic he had one in his pocket. A cannon-ball ricocheted against his breast, but the tragedy saved him. The missile had not strength to go beyond the third act."—*Bristol Medico-Chirurgical Journal.*

Very Mortal.—A Bristol newspaper, one day last month, in giving an account of a recent death, of which the cause was at first doubtful, said that the doctor had "stated that death probably resulted from typhoid fever and autopsy." The editor will perhaps be sorry to hear that there is no record of a patient having recovered from the last-named complication.—*Bristol Medico-Chirurgical Journal.*

OBITUARY.

CHARLES M. KING, M.D.

Dr. Charles M. King, an old resident of Germantown, died July 18, in the seventy-fourth year of his age. He was born in Roxborough, and when quite a young man was apprenticed to a paper-manufacturer at Manayunk. Early in life he made several whaling voyages to the South Pacific Ocean, and in 1849 he joined a party and went to the newly-discovered gold-fields of California, his party being among the first to cross the Isthmus by the Nicaragua route. In San Francisco he became a builder, and erected a number of large warehouses. In 1852 he returned East and entered the Baltimore College of Dental Surgery, and, on graduating, settled in Germantown, where he practiced for a time, and continued to reside, until his death.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

PROF. ALFRED STILLÉ, PROF. WM. GOODELL, PROF. D. HAYES AGNEW, PROF. H. C. WOOD, PROF. R. A. F. PENROSE, PROF. WM. PEPPER, University of Pennsylvania, PROF. J. M. DACOSTA, PROF. ROBERTS BARTHOLOW, Jefferson Medical College, PROF. CHAS. K. MILLS, Philadelphia Polyclinic.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

PRIVATE HOSPITAL FOR NERVOUS DISEASES

3240 Chestnut Street,

PHILADELPHIA.

THIS institution is designed to combine comfortable surroundings with the appliances and advantages of a special hospital. *Particular Provision is made* for the use of electricity, massage, rest and regulated exercise in neurological work, and for the use of strong electric currents in the treatment of abdominal and pelvic tumor cases.

Clinical Lecture.

AORTIC REGURGITATION WITH ANEURISM OF THE SUBCLAVIAN ARTERY.—REMARKS ON ANEURISM OF THE AORTA.

BY JAMES TYSON, M.D.,

PHYSICIAN TO THE PHILADELPHIA HOSPITAL AND PROFESSOR OF GENERAL PATHOLOGY AND MORBID ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA.

[Reported by William H. Morrison, M.D.]

Gentlemen: The patient before us is sixty-three years of age, and has no family history which bears upon his present disease. He had scarlet fever in early life, another fever, the name of which he does not remember, and later he had acute rheumatism, but otherwise he has been healthy. He denies having had syphilis, but admits that he has been a moderate drinker. He was admitted to the hospital, complaining of cough with expectoration of frothy mucus, with pain over the infra-axillary regions, and in the epigastrium. He was weak and exhausted, but had no subjective symptoms of disease of the blood-vessels. Physical examination, however, promptly discovered a very irregular heart and a murmur heard everywhere over the anterior portion of the thorax. His face was flushed and his breathing rapid. When I first saw him, the cough had been relieved, but auscultation easily recognized the murmur referred to. On superficial inspection of the chest, nothing unusual can be seen, but more careful examination discovers a pulsation just above the centre of the left clavicle. On close inspection, also, we notice a slight prominence in that situation. Placing my hand over the swelling, a distinct impulse is conveyed to it. These two signs—a *tumor* and an *impulse*—of themselves suggest aneurism, but there are other signs as easy of recognition. Thus there is impaired percussion-resonance over this area of usually clear percussion, and auscultation also gives us valuable signs. Placing the stethoscope over the apex of the heart, a murmur is discovered which is diastolic in time—that is, alternating with the first sound—a time when the auriculo-ventricular orifices are open and the aortic and pulmonary valves should be closed. Carrying the instrument toward the middle of the sternum, I observe that the murmur becomes louder and rougher, and louder still as the neighborhood of the aortic valves is reached. Finding this murmur at this place at our first examination, we made the diagnosis of aortic regurgitation, and thought it complete, whereas it was but partial. Placing the stethoscope over the tumor, I find the same murmur louder than at the apex, indeed quite as loud as at the base. I therefore conclude that the murmur heard over the apex of the heart is conducted from the aortic orifice, as it should be, with the regurgitating blood, but is conducted more loudly with the larger column toward the aneurismal sac. Again placing the stethoscope over the tumor, and listening a little more acutely, I find a second sound, less loud, alternating with the noisy one just described, the two sounds corresponding to the sounds of the heart. This fainter systolic sound is undoubtedly produced in the aneurismal sac, and is probably due to the blood passing over the roughened surface of the aneurismal wall. Sometimes these two sounds more closely resemble the normal

sounds of the heart, thus repeating them, as it were. More frequently but one is present—that corresponding with the first sound of the heart—than which it may be louder and more prolonged. In this instance, however, it is feebler while it is that corresponding to the second sound, which is louder, rougher, and more prolonged. This, however, has probably nothing to do with the aneurism, and is due to the aortic regurgitation; but this simulated duplication of the heart-sounds, an impulse, and the presence of a tumor constitute a triad of symptoms of aneurism unmistakable when present, while any one or all may be absent and any one simulated by some other condition. Take, for example, the murmur. In this particular case, the loudest factor of the aneurismal double sound is actually not aneurismal, but aortic in its origin. Again, a tumor may appear which is not due to aneurism; but such a mistake is less likely, because there is a great difference between a tumor due to aneurism and one dependent upon other causes, such as cancer, abscess, etc. Such a tumor is hard and unyielding, except sometimes in abscess, and non-pulsating, whereas in an aneurismal tumor the swelling is soft and there is a pulsation within the tumor. It is true that a tumor situated over a blood-vessel may exhibit an up-and-down movement due to the impulse communicated to it by the artery beneath; but such a pulsation differs from that of aneurism in that the tumor is raised *en masse*, while the aneurismal impulse is *expansile*.

A murmur or bruit is also often the result of pressure on a blood-vessel, but such a sound is apt to be soft in character, and such as you can yourself produce and hear by pressing upon the temporal artery as it runs in front of the ear. This murmur is very different in character from that produced by the vibration of the walls of the aneurism over which the blood flows. Finally, as has been said, an aneurism may exist without any murmur whatever.

Another very distinctive sign, which may also be absent, is the aneurismal thrill or tremor which is produced by the vibration of the walls of the aneurismal sac, and felt by the hands. It is noted in some cases with great ease, but is absent in this case. The thrill is a symptom which may come and go.

These are the signs of aneurism in almost any one of the great vessels. Others depend largely upon the locality, which let us seek to determine in the present instance. It has been seen that the pulsating tumor is above and behind the left clavicle, and in this location it can scarcely involve any other artery than the subclavian. If you will recall your anatomy, you will remember that the left subclavian is the third in order of vessels arising from the summit of the aortic arch. It ascends vertically to a distance equal to the innominate artery, and then curves outward to the left, between the anterior and middle scalene muscles, where it passes over the first rib, but under the clavicle, after which it becomes the axillary artery.

Among the most common symptoms of aneurism, in addition to those already noted, are those of pressure.

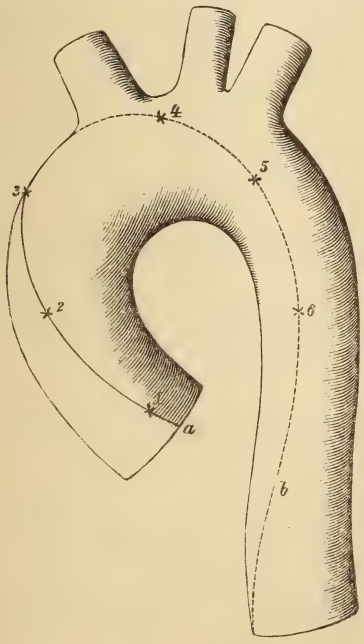
In this case of aneurism of the subclavian artery, we have no reason to look for encroachment, either upon the œsophagus, causing difficulty in swallowing, or upon the trachea, interfering with respiration, or upon the recurrent laryngeal nerve, causing alterations of the voice, or upon the vertebræ, or even upon the clavicle, although, when the subclavian aneurism becomes large, it may exert pressure upon the clavicle, give rise to great pain, and, in the course of time, to gradual erosion.

So, too, an aneurism may cause some alteration in the pulse, this varying with its situation. We should not look for any marked differences in the two radial pulses in this case, because the aneurism involves the subclavian, which, in its continuity, forms the radial artery. If it were an aneurism of the arch of the aorta, it might press upon the subclavian or the carotid artery, and in that way cause alteration in the pulse, so that a small pulse in the radial artery may be the result of aneurism of the arch of the aorta.

Passing again to the subject of aneurism of the aorta and of the great vessels of the neck, we find in the study of the former that there are certain sites which are more prone to dilatation than are others. These are the points against which the column of blood, as it passes from the heart into the aorta, impinges most strongly. As you know, the blood is sent through the aortic orifice by the ventricular systole with a sort of a twisting motion. As a result of this twist, there are different parts of the wall of the aorta which successively receive the force of the impulse. Thus, a spiral line of impingement is produced, beginning on the anterior face of the aorta and extending gradually around until its posterior face is reached. This is admirably shown in the accompanying diagram, from the sixth and

last (German) edition of Prof. Rindfleisch's excellent text-book of pathological histology. In this diagram, the solid black line is intended to indicate that part of the anterior face of the aorta which is thus impinged upon, while the dotted line is drawn on the posterior wall.

We observe that in the anterior line there are three situations, indicated by the numerals 1, 2, 3, at which aneurism of the arch of the aorta is most likely to make its appearance; and, knowing the direction of pressure in each instance, and reasoning backward from its effects, we are enabled to indicate the precise spots at which the aneurism began. Three points, indicated by the numerals 4, 5, and 6, are likewise found on the posterior surface. The first situation (*a* 1) is just above the aortic leaflets and in front of the origin of the pulmonary artery. An aneurism which starts at this point tends to drag upon the aortic orifice so that the lunulæ of the aortic valve are not able to completely close it, and consequently there is aortic insufficiency. In the case before us, the aneurism is too far away to produce such insufficiency. Further, as the tumor enlarges, it presses upon the pulmonary artery and interferes with the



passage of blood into the lungs. The right ventricle hypertrophies in its efforts to overcome this obstruction. To this sometimes succeed insufficiency of the tricuspid valve and venous pulse. When this aneurism ruptures, it empties for evident reasons into the pericardial sac, and is a not infrequent cause of sudden death in cases in which no disease had been suspected.

The second seat of aneurism (2) is more central in its situation and is the most frequent point of beginning of aneurism of the ascending aorta. The aneurism is immediately under the sternum and usually approaches the latter bone at the junction of the body with the handle. Continuing its progress in the direction of least resistance, it bores its way through the sternum, and finally the integument becomes its only covering. When rupture takes place, the blood escapes into the subcutaneous tissue, or the skin may rupture and the blood be discharged externally.

The third situation (3) is the antero-lateral wall of the convexity of the arch of the aorta, whence the aneurism pushes its way toward the apex of the right lung, which is the direction of least resistance. The firm bony bodies of the vertebræ resist its movement in the opposite direction, and it is forced up toward the apex of the lung. Consequently, we have first agglutination of the pleural surfaces by adhesive inflammation, and later rupture into the smaller bronchi of the right lung; whence the fatal hemorrhage is apt to be ushered in by hæmoptysis.

The next situation (4) is at a point midway between the innominate and left carotid arteries, whence the aneurism extends upward toward the trachea. Before reaching the size of a hen's egg, this aneurism, which usually has a constricted neck, perforates the trachea. Before this happens, however, the aneurism, by the pressure which it exerts, gives rise to tracheal symptoms and to alterations in the voice which in the earlier stages are often mistaken for those of laryngitis. When this aneurism ruptures, it is generally into the trachea.

Just beyond the left subclavian artery, between it and the isthmus of the aorta, in the descending limb of the arch, we find another position (5) in which aneurism occurs and is disposed to work its way posteriorly, and to the left toward the vertebræ. Not infrequently there is a cylindrical dilatation of the entire aorta anterior to the isthmus.

The remaining aneurisms of the descending arch all tend more or less to work backward, eroding the vertebræ, sometimes opening the spinal canal, and producing symptoms of paralysis. The above are the situations in which aneurisms of the aorta are

most likely to occur. The point of origin of the great vessels is often a seat of aneurism, for the reason that there is always some resistance where one vessel branches from the other, and this favors dilatation.

Why do aneurisms occur? What is there in the condition of the individual or of his blood-vessels which will tend to the production of aneurism? I do not believe that an aneurism can occur in a blood-vessel whose wall is perfectly healthy. For the production of aneurism, it is essential that there be some weakness in the vessel wall This is occasionally the result of injury, but far more frequently is due to a fatty degeneration in the intima not always brought about in the same way. It is most frequently due to chronic endarteritis or chronic inflammation of the coats of the blood-vessel, and constitutes what is known as atheroma. Another cause is the so-called "fatty erosion," said to occur independent of inflammation. This is most frequently the starting-point of that variety of aneurism known as dissecting aneurism, where the blood, perforating the inner coat at a single point, dissects its way for some distance between the inner and outer coats. But by far the more frequent cause of aneurism is endarteritis, and the resulting atheroma. The causes of endarteritis are various. The most common is perhaps alcohol. Unquestionably blood loaded with alcohol is one of the most potent causes of this inflammation. Syphilis is another fruitful cause of chronic inflammation of the lining of the aorta. The habit of "free living," as it is called, is very prone to produce this condition. The poison of gout is another cause. It is possible that the defects in nutrition which always attend advancing age, and which come at different ages in different persons, may be sufficient to produce this fatty erosion, but they are not sufficient to produce endarteritis. Given these predisposing causes of aneurism, the impulse of the blood is by far the most usual exciting cause. In addition to this, there may be obstruction to the flow of the blood, which may contribute to the dilatation. Thus the pressure of a tumor on a blood-vessel, conjoined with an atheromatous condition, may lead to the production of aneurism. Whether or not, in the absence of any of the predisposing causes of aneurism, any obstruction is sufficient to produce the dilatation, is, as I have said, doubtful.

Treatment.—The question of practical importance is of course the management of a case of aneurism. I say freely that I have not been satisfied that any of the measures from time to time proposed, except surgical procedures, are of much service. Of remedies suggested, the iodide of potassium has perhaps the largest reputation and is most generally used. I have systematically and thoroughly tried it, but I have never been able to see that it does the least good. Electrolysis has been used by others with somewhat varied results, but I have never seen enough evidence to encourage me to make use of it. Compression in the case of vessels like the subclavian has been useful, either in curing the aneurism or temporarily preventing its extension. Surgical operations by ligation, either on one or the other side of the aneurism, are the most certain methods of cure, where an artery is accessible. Operation in aneurism of the aorta is of course impossible; but, in the innominate, carotid, and subclavian arteries, ligation has been used with success, and, where the immediate effect of the operation is not unfavorable, a cure may be expected. It may, however, happen that the blood-vessel is so atheromatous that it is disposed to reproduce the condition, and this point must be borne in mind in deciding whether or not an operation shall be performed. If there is atheroma, the operation will be likely to be a failure.

In those cases in which an operation is not possible, the treatment is that suitable for a case of heart-disease: quiet, rest, absence of excitement and exposure. Such a course will prolong the life of the patient and prevent the enlargement of the aneurism, which sooner or later must be fatal.

COMMUNICATIONS.

ANTIPYRIN, ANTIFEBRIN, AND PHENACETIN IN THE TREATMENT OF PULMONARY CONSUMPTION.

BY THOMAS J. MAYS, M.D.,
PROFESSOR OF DISEASES OF THE CHEST IN THE PHILADELPHIA POLYCLINIC

Although these therapeutic agents have been but recently introduced to the profession, their range of usefulness already extends over a wide domain of practical medicine; and, although it is quite certain that in many instances their virtues are greatly overestimated, I think the practical results which will be offered in this paper show that if these substances are properly administered they form a most valuable and important addition to the therapeutics of pulmonary

consumption. In common with the practice of the day, I gave antipyrin for several years solely with a view of obtaining its febrifuge properties, and, while there can be no question regarding its power in this respect, more recent experience has taught me that this is not its only mission, and that it is a serious mistake to discontinue its use in cases of phthisis after the elevated temperature has been reduced very nearly or altogether to a normal point. Experimental research and the successful employment of these drugs in other diseases, notably in chorea, epilepsy, neuralgia, gout, and chronic rheumatism, which are unaccompanied by fever, point out that they possess an undoubted action on the nervous system, and their great utility in the treatment of phthisis is probably entirely due to the marked stimulating influence which they exert on this structure of the body. The remedial value of these agents is therefore not fully obtained unless they are continued after their use as antipyretics has ceased; for there is much reason for believing that the fever, the inflammation, the dyspnœa, the anorexia, and many other collateral processes in pulmonary phthisis are in a great measure dependent on disordered innervation, and that the remedy which controls the first-named symptom will also control the others. This distinction between the purely antipyretic action of these drugs and their power to counteract the other disorders is too important to be overlooked in the treatment of this disease. In my earlier observations on the clinical effects of antipyrin, I often noticed that, in giving it to phthisical patients with a high temperature and with a hopeless physical condition, the fever came down at once, and an improvement immediately followed in the accompanying conditions. I have notes of several cases, one of which I will briefly relate, in which the most surprising results occurred. A young woman, aged 19, with a large cavity in one apex and general destruction going on in the other lung, consulted me in June, 1885. I attended her, off and on, during that summer and autumn, without being able in the least to make an impression on the rapid progress of the disease, until the following October, when, at a loss what else to do, I prescribed ten grains of antipyrin, forenoon and afternoon. In spite of the small size of the dose, which was given in order to avoid the production of a serious collapse—a view which prevailed at that time—a complete transformation in her whole condition took place. Her fever came down, of course, but the cough and expectoration also became less, the night-sweats ceased, her appetite and general strength improved, and she felt better in every way. The disease had, however, already produced too serious inroads on her health to hold out much encouragement toward the prolongation of life, and she died the following December. The valuable lesson which this case should have taught me at the time was wholly overlooked, because I was imbued with the prevailing belief that, after the full antipyretic effect of antipyrin had been secured, it became a superfluous and perhaps a harmful agent, and would have to be discontinued.

So little impression did this case make on my mind as to the true and permanent remedial effect of antipyrin in phthisis, that I then failed to appreciate the import of a very interesting paper by Dr. J. Holland, of St. Moritz, Switzerland, which appeared in the *Practitioner*[1] about the same time, and in which he reports a series of cases of phthisis also treated with antipyrin; and evidently, like myself, administered the drug then only with a view of obtaining its febrifuge action, although, in the light of our present knowledge of its action, it is quite evident that it played a deeper rôle. His results were, however, so striking and in such perfect harmony with what I have since witnessed myself that I shall take the liberty of quoting the history of some of his most noted cases.

"*Case I* (Holland).—In last July (1884), I was consulted by a lady who was in advanced consumption. That morning, she had spat up about two teaspoonfuls of blood, and, on examining her chest, I found a cavity at the left apex, with extensive softening all around it; there was also softening at the right apex in front, but over a limited area; the cough was particularly troublesome, and appeared to be out of proportion to the amount of expectoration, although this was considerable. Her high temperature persisted and rose daily to about 102°; indeed, during the last week, it had on three occasions reached 103°, being highest from 4 to 6 P.M. Her temperature at my first visit was 103.2°. I advised total rest in bed, a light nutritious diet, a dose of Carlsbad salts the first thing in the morning, to be followed by ⅛ gr. morphine, and ⅛ gr. digitalis leaves every three hours. Next morning at 10.30, her temperature was 101.4°; in the evening, 103°. Instead of the digitalis, I now prescribed fifteen grains

[1] Antipyrin in Phthisis and other Febrile Disorders. Practitioner, vol. xxxiv, p. 521.

sodium salicylate every three hours. The night of the same day, her temperature again rose to 103.6°, and her cough was more troublesome. I now determined to try something else, and gave her twenty grains of antipyrin every three hours while awake, until three doses had been administered. The next afternoon, I saw her at the usual hour, and, directly I entered the room, I noticed how much better she looked. She told me she had taken the first dose of the antipyrin on the previous evening at 6 o'clock, and in less than an hour afterward she felt more comfortable and less feverish; at that time, she found her temperature 101.6°. At 9 P.M., just before taking the second powder, it was exactly 101°, and, at a quarter to eleven, 100.4°. She had slept well, only waking up when the cough troubled her, had eaten better, and altogether felt herself much better and more comfortable than she had done for weeks. The next evening, her temperature registered 100.4°. My patient complained of no disagreeable or unusual sensations. I could discover no altered physical signs in the chest, and there had been no evacuation of large quantities of expectoration, or anything else that could account for the fall of temperature, except the action of the drug itself.

"On the fifth day, she reported: 'Temperature at 9.30 last night, when I took another powder, exactly 100°, this morning at 9 A.M., 98.8°; at 2 P.M., when I took my first powder, it was 99°. Had a good night, cough and expectoration not so troublesome, no perspiration, taking more food, and feeling very much better.' During my visit on this day at 5 P.M., her temperature was 99.2°. I ordered another powder at 8.30 P.M., and two hours afterward the temperature was normal. Sixth day: Patient had a good night, cough and expectoration still diminishing, no perspirations, appetite and digestion good, spent two hours out of bed. Temperature 9 A.M., normal; 2 P.M., 98.8°, at 5 P.M. normal, and at 10 P.M. normal. Took a powder at 2 and at 6 P.M. Seventh day: Fairly good night, cough and expectoration a little more troublesome than the night before, but slept well on the whole; appetite and digestion good; no perspirations; spent four and a half hours out of bed. Temperature at 5 P.M., 99°; took a powder at 2 and 6 P.M. Eighth day: Temperature normal all day; took two powders. Ninth day: Same report. My patient continued the antipyrin twice a day for four days longer, and once daily for about a week afterward. During this period, she had only an occasional elevation of temperature, the highest registered being 100°. Her cough improved, the expectoration became less, and she was able to take carriage-exercise. In a month from the time I first saw her, she had gained three pounds in weight and she only coughed and expectorated in the mornings. The physical signs had improved in proportion, for the softening at the right apex had cleared up, and had conspicuously diminished around the cavity at the left side; the cavity itself showed signs of healing, and freer breathing was heard all over the left lung." He further states that this patient spent the following winter at St. Moritz, gained fifteen pounds in weight, temperature nearly normal since the previous August, became able to walk ten miles with very little fatigue, her appetite and digestion remaining excellent.

Case VI (Holland) (Abstract).—A woman with troublesome cough consulted him in July, 1884. She had a bad family history, and her chest showed moist sounds in both apices. Evening temperature, 100°. Prescribed bitter tonics for her, with antipyrin, and sitting outdoors all day long. She lost her fever at once and improved rapidly, both lungs drying up quickly. So far as he knew, she had no recurrence of the attack.

Since the publication of Dr. Holland's paper, several other antipyretics have been brought to the attention of the profession. Among the most valuable of these are antifebrin and phenacetin. The former is well known already, and the latter bids fair to become its successful rival. About a year ago, directly after its discovery was announced, I received a small quantity of phenacetin through the kindness of Mr. Merck, with which I made some clinical observations, the results of which were published in the *Medical News* for August 20, 1887, under the title of *The Effects of the Latest Febrifuge, Acetphenetidine*, as it was at first known. Altogether the drug acted very favorably, and I have at intervals continued its use since then. Its action is as decided as that of antipyrin and antifebrin, and it is said to be less liable to produce toxæmia. The first case in which I gave it was one of acute phthisis, with an afternoon temperature of 105.2°, which was preceded by a chill. She received three grains of the drug every three hours. The next afternoon she had another chill, and her temperature was 104°. The third day she

had no chill, and her afternoon temperature had sunk to 101°. The fourth day she had another chill, but her afternoon temperature only rose to 101.2°. The fifth day her temperature was down to 98°, and the phenacetin was discontinued. On the sixth she had no chill, but her temperature rose to 101° P.M. Seventh day: Chill, afternoon temperature 103.4°. Resumed the drug. Ninth day: Afternoon temperature 100.8°. Tenth day: Afternoon temperature 100.6°. At this point the supply of the drug became exhausted. The other case was one with an old cavity and a temperature in the evening of 102°. He received the same dose. Second day: Afternoon temperature 101.4°. Third and fourth days same, fifth day 100°. It was quite obvious, from even this limited experience with the drug, that it had a marked influence in depressing the temperature, and, beside this, it seemed to improve the cough, expectoration, appetite, and the general condition of the two patients. Subsequent use of the drug showed me that I gave it in too small doses in these cases. It is a valuable antipyretic, and, were it not for its expensiveness, which is even greater than that of antipyrin, it would soon become very popular; but, so long as the same results can be obtained by antipyrin, or by antifebrin, which is the cheapest of all the antipyretics, its consumption will probably be rather limited. I think, however, that in giving these agents it is a good plan to occasionally alternate one with the other. Very frequently one of them disagrees, as in the case of antipyrin, which sometimes produces urticaria, or as in that of antifebrin, which brings about lividity of the lips, gums, finger-nails, etc., and then it is very advisable to resort to phenacetin, which is believed to be free from evil consequences.

One thing must always be remembered in the administration of any of these agents, and that is that small doses, which are usually available in the reduction of the fevers of acute diseases, are practically useless in subduing the fever of chronic phthisis. Eight or ten grains of antifebrin and phenacetin, and twelve or fifteen grains of antipyrin every four hours, are small enough doses to begin with, and frequently they will have to be largely increased before the desired results are secured.

I shall now present the histories of a few cases of phthisis which were treated chiefly either with antipyrin, or antifebrin, or with both, in order to demonstrate the salutary influence of these drugs in this disease.

Case I.—W. T., man, aged twenty-three, was first seen March 27, 1888. He then had a cough which had lasted for some time, a profuse yellow-whitish expectoration, no hæmoptysis, was losing flesh (weight 109 pounds), appetite poor, tongue coated, had chills, fever, and night-sweats. His mother, father, and one sister died of phthisis. Physical signs, right lung: Tympanitic percussion-sound in apex, indicating a cavity extending to second intercostal space in front. Dulness from this point to base of lung in front, and from apex to base behind. Moist crackling over cavity, and crepitation and subcrepitation over the remaining portion of the lung anteriorly and posteriorly. Afternoon temperature 102.6°. March 28, afternoon temperature 104°; antifebrin, four grains every three hours, inhalation of 25 per cent. aqueous solution of ichthyol through respirator. April 3, cough less, temperature 101°; same treatment. April 9, temperature 104°; seven and a half grains of antipyrin every four hours with the ichthyol inhalations. April 20, P.M. temperature 102°; same treatment. May 7, P.M. temperature 100°, cough and expectoration very much less, night-sweats diminished, appetite very good, and his strength is improved. May 14, appetite good, P.M. temperature 102.5°; same treatment. May 28, P.M. temperature 101°. The antipyrin now produced its characteristic eruption, is discontinued, and ten grains of antifebrin every three hours are substituted. June 26, coughs and expectorates but very little, appetite very good, P.M. temperature 100°. July 6, feels very good, P.M. temperature 100.5°, weight 116 pounds; same treatment. Physical examination shows that the dulness in front from second intercostal space to base of lung had disappeared, and that the dulness behind had markedly diminished. No moist râles audible anywhere except some crackling over cavity-area. Cavity is much more dry than when first seen. His trade is an outdoor one, and he has been at it for some time.

Case II.—July 3, 1888, L., woman, aged 21, had pleuro-pneumonia two and a half years ago, has now a cough and yellow expectoration for six months, is losing flesh, poor appetite, night-sweats, and temperature of 104.25°. No family history of phthisis. Physical signs, left lung: Cavity in left apex; below cavity to base, exists an abundance of râles anteriorly and posteriorly. Right lung: Mucous râles over whole lung. Eleven and a quarter grains of antipyrin every four hours. July 7, she felt better,

appetite improving, and she had a temperature of 102.6°; twelve grains of antifebrin every four hours. July 10, temperature 101°; same dose of antifebrin every three hours. July 12, cough and expectoration much better, boil in left axilla, eats good, temperature 102°. July 14, feels better, temperature 101°; same treatment. July 16, appetite good, night-sweats less, temperature 99.5°. July 20, temperature 101.2°, appetite good. July 28, feels very good, eats well, temperature 98.5°. Temperature was taken only in the afternoon. Still under observation.

Case III.—Woman, aged thirty, was first seen May 8, 1888. She has been coughing for eight years, expectoration profuse and of a gray color, no hæmoptysis, but was losing flesh, had night-sweats, no appetite, irregular bowels, tongue coated, œdema of both insteps, temperature 104°, weight 90 pounds. Physical signs show a large cavity in upper third of right lung, with crepitation in extreme end of apex. Mucous râles from cavity down to base, anteriorly and posteriorly on same side. Crepitation at apex and base of right lung. Chest and whole body very much emaciated. She received seven and a half grains of antipyrin every four hours with ichthyol inhalations. May 12, her temperature was 101.25°, her cough was better, and expectoration had markedly diminished, the appetite improved, and she said she felt stronger. May 26, temperature 100°, felt very much better; antipyrin was increased to eleven and a quarter grains every four hours. June 5, temperature 99.8°, felt very good. June 8, temperature 101.5°; antipyrin was now increased to fifteen grains every three or four hours until up to the present writing, the temperature being generally 99° or 99.5°, only rising once to 101°. She is now and has been for some time able to take from one quart and a half to two quarts of milk, three-quarters of a pound of raw beef, an egg, and raw beef suppositories per day. The night-sweats are improved, the œdema of the feet has disappeared, and, although she has not gained much if any in weight, she looks and feels quite different. Some days she has taken as high as seventy grains of antipyrin, without producing more disturbance than a slight lividity of the lips and finger-nails, and a rash which appeared only during the last week. She was at once placed on eleven and a quarter grains of antifebrin every three hours. The beneficial effects of antipyrin became manifest directly after its first administration, and have certainly continued up to the present time. The temperature was taken in the afternoon.

Case IV.—P., man, aged thirty-five, came under my care June 21, 1888, with the following history: Well until last January, when he was taken with a chill, began to cough and expectorate yellow sputum, had slight hemorrhages, appetite poor, tongue coated, lost flesh, and afternoon temperature 101°. Two of his sisters died of consumption, aged sixteen and eighteen years respectively. Physical signs: No impaired percussion-resonance, sibilant and subcrepitant râles in both apices, and crepitation at bases of both lungs, marked especially in lateral and posterior areas. Beside these, there are distributed small areas of subcrepitation over different parts of both lungs, especially the left at the intersection of the sixth rib with the nipple-line. Treatment, six grains of antifebrin every three hours, inhalation of compressed and rarefied air, pulmonary gymnastics, a nutritious diet, and flaxseed poultices. The antifebrin in the course of a few weeks was increased to twelve grains every three hours, his temperature gradually sank, he improved in cough, appetite, and strength, and, on the 25th of July, when his afternoon temperature was normal and had been so for some time, his chest showed the following physical signs: Very few râles in right and none in left apex, few crepitations at base of left lung, chest-movements very much increased. In this time, he gained one pound and a half.

Case V.—C., man, aged thirty-four, consulted me May 9, 1888. Cough and expectoration since previous July, losing flesh, poor appetite, coated tongue, dyspnœa, and an afternoon temperature of 101°. Weight 110 pounds. Physical condition: Cavity in left apex, and mucous râles distributed over same lung; right lung normal, although whole chest is very flat and immobile. He was treated chiefly with antipyrin and pulmonary gymnastics. His temperature also came down, and he began to improve in every respect. On the third of July, he weighed 117½ pounds.

I could quote many other cases in support of the practical usefulness of these agents in the treatment of pulmonary consumption, but they would demonstrate no more than what has already been shown. I do not wish to convey the meaning that they are specifics, but I do mean to say that they are most important levers with which we are able to stay the fever, tone up the nervous system, improve nutrition, and compel the disease to give us time and opportunity to

feed the patient and to modify the local condition of the lungs by external applications, pulmonary gymnastics, physical exercise, etc.—most essential considerations in the therapy of this stubborn disease.

EPILEPSY DUE TO STENOSIS OF THE INTERNAL OS UTERI: OPERATION; CURE.

BY WILLIAM A. CAREY, M.D.,
ASSISTANT PHYSICIAN IN DISPENSARY FOR DISEASES OF WOMEN, UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

That an earnest and exhaustive effort should be made in every case of epilepsy, to determine whether the affection is due to a central lesion, to an alteration of the blood, or to a peripheral irritation, is becoming better appreciated as the record of "reflex" cases is multiplied. The list of causative lesions is increasing, and it will continue to increase as greater thoroughness is used in the search for etiological factors. Attention has recently been called to a hitherto unsuspected possible cause of epilepsy and various other nervous disturbances, namely, insufficiencies of the ocular muscles.[1] It has been generally conceded that epilepsy in the female may be due to uterine or ovarian irritation, and, in fact, it has been so frequently and perhaps so improperly referred to this that a reaction has taken place, leading to the opposite error of ignoring such lesions as probable factors in causing epilepsy. Dr. Allen McLane Hamilton, writing of epilepsy, in the "System of Medicine by American Authors," says: "Reflex causes play a prominent part in many instances, though I am inclined to think that their importance has been greatly exaggerated. This is especially true of so-called uterine epilepsy." But he adds: "The fact that in some women we find *accès* at a period identical with menstruation points to a close relationship." A somewhat careful review of the literature of the subject shows only two reported cases in which epilepsy seemed to depend on conditions similar to those in the case whose history I shall give.

The first of these cases was reported by Dr. M. A. Pallen, in the *St. Louis Medical and Surgical Journal*, 1869, under the title of "Dysmenorrhœic Epilepsy and Sterility." In this case there was stenosis of the internal os uteri, for the correction of which the cervix was incised, and, after making a few alterative applications to the mucous membrane, to relieve an endometritis which had been produced by the anatomical defect, the dysmenorrhœa and epilepsy disappeared. The other case was reported in the Detroit *Lancet*, 1880, by Dr. J. H. Carstens, under the heading of "Epilepsy due to Uterine Stenosis." Here a girl, æt. 17 years, had menstruated regularly for three years, when, upon "catching cold," the menses suddenly stopped. Two months later, upon their reappearance, there was dysmenorrhœa with epileptic convulsions. These symptoms persisted through eight menstrual periods, when, upon the discovery of a constriction of the uterine canal at the internal os, rapid dilatation was performed, and the trouble disappeared for three months. At that time the patient was again under observation, having experienced pain and dizziness during the last menstrual epoch.

The following case shows a longer period of illness existing prior to operation, and exhibits a more satisfactory result—ten months having elapsed, during which time the patient has been entirely free of her former trouble.

Mrs. F., æt. 24 years, blonde, well developed, weight 130 pounds. Married five years, and sterile, although it is stated that, about six months after marriage, she miscarried at three months, after lifting heavy furniture. The patient came under my observation September 16, 1886. When first seen, she was in bed, unconscious, with flushed face and hot dry skin. There were twitchings of the muscles of the face and extremities, with an occasional tossing of the arms and clenching of the fists; also grinding of the teeth, but no biting of the tongue, nor decided frothing of the mouth. Occasional groans were uttered, as if the patient were conscious of severe pain. The respiration was not embarrassed. Temperature, 104.6° F.

Consciousness returned at intervals, to be succeeded by unconsciousness and the convulsive movements above described. This condition lasted for an hour, and was followed by a deep sleep, prior to which the patient said she felt much better and was relieved of the pain in the head, pelvis, and thighs. The following history was obtained: Attacks similar to and graver than the one described had been frequent during the past two years. They bore a close relationship to the menstrual molimen,

[1] Functional Nervous Diseases, by Dr. Geo. T. Stevens, of New York. Paper entitled "Graduated Tenotomy in the Treatment of Insufficiencies of the Ocular Muscles," by Dr. Charles H. Thomas, MEDICAL AND SURGICAL REPORTER, March, 1888.

occurring during the continuance of the discharge, or preceding or succeeding it by a period varying between one and four days. This attack occurred while she was menstruating, the discharge having appeared two days previously, and was accompanied with a slight chill and considerable pelvic distress. The following day, all untoward symptoms had disappeared, with the exception of a dull headache. The diagnosis was epilepsy, although the symptoms in this attack were not as sharply defined as they were on subsequent occasions. The pyrexia during an attack was never so marked afterward. Although a rise of temperature usually occurs during and after the second stage of such attacks, it is not generally so high as in this case. After the lapse of four months, the patient reported, with these additional symptoms: Severe headache, frequent micturition, dysmenorrhœa, obstinate constipation, and various nervous phenomena, including a complete change of disposition and marked failure of memory. Domestic duties, which formerly were performed with interest, now bore heavily upon her; social ties were disregarded, and her bearing toward those about her was noticeably altered. She remained in her room much of the time, and was disposed to melancholy. Previous to marriage, three years before, she considered herself perfectly well. There was no family history elicited which threw light upon the origin of her illness. She was inclined to trace it to the miscarriage. The dysmenorrhœa began after this mishap, but there was no suspicion of retained membranes, for there was neither menorrhagia nor metrorrhagia. Considerable pelvic inflammation doubtless attended this accident, for she was confined to bed for about four weeks subsequently. Menstruation was somewhat irregular afterward, recurring at intervals of from three to five weeks. Dysmenorrhœa was sometimes so severe as to require medical attendance. The character of the pain was indicative of an obstruction to the discharges—pain occurring at intervals, and being relieved by the escape of blood-clots, the pressure of which had probably distended the uterine canal. A vaginal examination revealed a small uterus, with a hard conical cervix, which was pointing in the direction of the vaginal outlet. The external os was rounded and small; the fundus anteflexed and pressing on the bladder. The introduction of the sound beyond the internal os was accomplished with difficulty. The condition was anteflexion and stenosis of the internal os uteri. Rapid dilatation of the canal of the uterus was advised, with a view to relieve the pain attendant upon the monthly sickness, rather than in hope of curing the epilepsy, which was steadily growing worse.

This measure was not carried into effect, however, until five months after its recommendation. During this interval, she had five attacks similar to the one described. They were centred around the menstrual nisus in the following manner: February, 1887, within five days after the cessation of the discharge; March, just at its close; April, on the first day of the flow; May, four days previous to the appearance of the discharge. Fifteen days afterward, she had a severe epileptic seizure while visiting a relative. This was the fifth grave attack, in addition to the monthly convulsive derangements, during a period of two years. This characteristic seizure, which exhibited all the well-known features of epilepsia gravior, did not occur sufficiently near the menstrual period to suggest a relation with that function, but two subsequent like attacks were experienced coincidently with menstruation. The monthly disturbance, which had recurred so regularly, was of the same nature as these more severe manifestations, differing only in degree. Of the latter, there were only seven attacks, while the former were experienced monthly for nearly two years, and were gradually developing into the graver form, their periodicity implying a close relationship between them and a perversion of the menstrual function. The uterine lesion explained the difficulty in menstruating, and its correction was followed by cessation of the convulsions, which were thus proved to have been simply reflex manifestations of uterine irritation.

On June 6, 1887, Dr. William L. Taylor dilated the canal of the uterus to 1¼ inches. Seven days after the operation, the menses appeared, and were so painless that she was not aware of her condition, except by the external appearance. Unfortunately, she did not remain in bed, as directed, but, feeling so comfortable, was imprudent enough to pay a visit, on the last day of menstruation, to a friend living at a considerable distance, and on her way home was overtaken by a thunder-storm, which she hurried to escape. This exertion, so soon after the operation, and just when the uterus and its appendages were especially susceptible, proved sufficient to provoke another fit. When only a square away from her home, she dropped to the ground in an unmistakable epileptic con-

vulsion. Successive convulsions occurred for about two hours. During a lucid interval, she mentioned the writer's name as her medical adviser, but, before she could give any information which would throw light upon her identity, she relapsed into unconsciousness and convulsive movements. It was after midnight when I saw her in the saloon to which she had been carried. She was removed to her home in a large rocking-chair, and soon afterward fell into a profound sleep, which lasted well into the morning and left her with a dull headache the following day. During the month of July, she was out of town, and, though she suffered some sharp pains while menstruating, they were not like those formerly experienced.

Upon returning to the city the following month, her general health appeared much improved, and it was chiefly this feeling of returning health that led to many indiscretions which retarded her recovery. During this month, she repeated the misfortune of June—by over-exertion during menstruation. The flow had begun without any pain, and she felt so well that much care seemed unnecessary. While walking along the street, she suddenly recognized an aura, and had time to ring the bell of a house and gain admittance just as she was seized with a convulsion. This was the most severe, and the last, epileptic attack which she has had. She was removed to her home on a stretcher furnished by the police department, and had several milder convulsions afterward, although a period of over two hours had passed since the beginning of the attack. As usual, a profound sleep succeeded, and left her quite well, excepting a feeling of heaviness the next day.

The cause of these two invasions of epilepsy after the operation was undoubtedly uterine irritation. This, however, was not due to any obstruction in the uterine canal, but to an excitation of the nerve-structures of the uterus and ovaries, inducing too great a flow of blood to the parts which had been rendered, for a time, hypersensitive by the operation. Had she remained in bed until after the congestion attendant upon the catamenia had entirely subsided, it is reasonable to suppose that she would have escaped the seizures. There is, necessarily, some congestion of the uterus and neighboring structures resulting from rapid dilatation of the uterine canal, and therefore it is natural to anticipate that the menstrual period immediately succeeding the operation will be possibly more painful than usual. The ovaries—one or both—are sometimes involved to such an extent that they undergo hypertrophic changes and become swollen and tender. It is evident, therefore, that the patient erred in making such exertion before the pelvic organs had recovered their normal circulatory and nervous equilibrium. During the following menstrual period, greater attention was paid to bodily rest, and not the slightest trouble was experienced. Instead of dysmenorrhœa and epileptic paroxysms, there were painless menstruation and perfect composure of body and mind.

Ten months have now elapsed since the last convulsion occurred, during which time she has improved in every respect. With the correction of the uterine defect, all the abnormal conditions—dysmenorrhœa, frequent micturition, epilepsy, headache, failure of memory, irritability, melancholy, and other symptoms expressing a general decline of health, have disappeared, and she now considers herself in perfect health.

The deduction to be made from the history is apparent: The epilepsy and accompanying derangements were due to constriction of the internal os uteri. This stenosis was a barrier to the free escape of discharges at the catamenia. The consequent engorgement irritated the nerve-supply and this peripheral irritation was transmitted to the central nervous system and manifested itself in epileptic paroxysms. While it is true that the bromides were administered at various times during the course of treatment, they were not relied upon for curative effects, and were not pushed for specific action. Indeed, they were first given to relieve the headache from which the patient suffered. General tonic and alterative remedies—iron, quinine, strychnine, arsenic, were prescribed for about six weeks early in the course, and nitrite of amyl was ordered to be inhaled in the event of an aura occurring. But, when the warning came, the vial was never at hand. The drugs thus administered can therefore scarcely be included as curative agents. This is apparently a case in which epilepsy originated and persisted because of a definite uterine lesion, the relief of which was followed by cure. It is not unreasonable to hope that in the future many cases of so-called idiopathic epilepsy may be recognized as reflex manifestations of ascertainable causes. Therefore, as the causes of epilepsy are almost as numerous as its victims, it behooves us to interrogate every organ and correct every abnormality which could possibly play the part of an irritant.

HEALING OF WOUNDS IN HIGH ALTITUDES.

BY W. N. SHERMAN, M.D.,
KINGMAN, ARIZONA.

It has probably not escaped the notice of the observant surgeon residing in the high places of the Rocky Mountains, how quickly and kindly the healing of all wounds takes place, and often under the most unfavorable circumstances. To me, this fact has presented a striking contrast with my experience east of the Mississippi River. My observation has extended over eight years of continuous practice in several localities of the Rocky Mountains in the Territories of New Mexico and Arizona, three years of this time in the capacity of a railway surgeon. The majority of wounds treated, however, have been gunshot wounds, including many of a miscellaneous character, and in localities from 2000 to 7000 feet above sea-level. Excepting a few cases of railway injury where the shock was great, the so-called capital operations resulted as favorably under the same conditions as did the minor surgical cases.

In this frontier country, men become accustomed to hardships and dangers, so that wounds that would be considered of a serious nature East are considered as trifles here; and often, when the sufferer would consult a surgeon, the distance or his isolation prevents it. Many a brave man, having been wounded by accident or otherwise, is taken to the rude camp of a kind friend, and then, under the care of unskilled comrades and the assistance of nature's antiseptic, he survives wounds to which, under circumstances apparently more favorable, he would have succumbed.

The aborigines, many of whom are the personification of filth, dress their wounds with dirty greasy rags, or bathe them in dirty water, and yet their wounds seem to heal as kindly as if treated antiseptically. These are stubborn facts to the enthusiastic advocate of the germ theories, but they are matters of frequent occurrence in this country.

My observations have not been confined to men alone. I have frequently been called upon to act in the capacity of a veterinary surgeon, and in the lower animals. I have noted the healing of wounds in a remarkable manner.

The conditions and surroundings under which the surgeon operates are often as unfavorable as those of the sufferer after the operation or injury.

Through necessity, the dressing of wounds and operations is sometimes performed in the field (outdoors), in the cabin of the miner, the hut of the ranchman, the Mexican adobe, an Indian "wickiup," a box-car, freight-house, or a dugout.

I need record but a few cases to illustrate the rapid manner in which wounds heal.

Case I.—D. H., aged 40 years, Mexican, miner, was injured by having a bucket of rock spilled upon his head while working in the bottom of a shaft. I saw the patient about 8 hours after he had received the injury; he was rational, had three large scalp-wounds and other bruises. I removed the hair from the region of wounds, washed them in spring-water, directed cold compresses, gave calomel grs. x, and left orders for the patient to be removed twenty miles, to town. I had discovered, as I thought, a fracture of the cranium, but did not ascertain its extent. The patient was lashed on a burro, and, with a comrade on each side, conveyed across the mountain 6 miles, from whence he was conveyed in a buckboard. He arrived about 24 hours after my first visit, and on examining his head I found the edges of the wounds quite firmly adhered by fresh granulations. I was greatly surprised at the rapidity of the reparative process, and used no little force to open the one over the seat of fracture. On further investigation, I found a marked indentation of the left parietal bone, at the margin of the coronal suture, about midway between the sagittal and squamous sutures. The extent of the fracture was small, and, as there were no signs of compression and no loose pieces of bone, I closed the wounds with adhesive straps and dressed them with hydronaphtholated olive oil. Patient complained of headache and restlessness; gave potass. bromide and chloral hydrate; relief followed, and in two days the patient left his room and walked next door to meals. In five days more, he returned to the mine, and went to work soon afterward. I ceased the daily dressing of the wounds April 1.

The fracture spoken of was very distinct, but may have been only of the outer plate. It seemed to have been made by the corner of a very sharp hard rock.

July 2, 1888. Saw this patient to-day for the first time since. He has been well, and worked steadily. There is still some depression in the cranium over the cicatrix, where the fracture occurred.

Case II.—I. C., aged 33, farmer, October 3, 1885, had his left arm caught in the machinery of a thresher. Primary amputa-

tion of arm above elbow. No antiseptics used, but otherwise dressed in ordinary manner. Patient progressed satisfactorily; stump healed in 21 days, and patient left bed. In 28 days, he resumed work with the thresher.

Case III.—R. M., age 23, car-repairer, was cut with razor in a drunken brawl. Wound below thyroid cartilage; a straight smooth cut, about five inches long, and extending across the front and lower part of the neck and through the skin and cellular tissues. Trachea was exposed, but uninjured. I was near the patient when he received the wound, and dressed it one hour afterward. Closed wound with twelve interrupted silk sutures. The patient resumed his spree, and, on the second day after the receipt of the injury, he resumed work. The wound was never dressed but the one time, and the patient wore a soiled silk handkerchief around his neck, which constituted the dressing. On the fourth day after receipt of the injury, he came to me to remove the stitches. The wound was completely healed, apparently by first intention.

I know of several instances in which men, desperately wounded, have fled from justice, taking refuge in open camps in the mountains, where, without medical or surgical aid, they recovered. I have seen operations performed in the most unscientific manner where perfect recovery followed, and men have acquired local reputations as surgeons who are shamefully illiterate and unskilled.

I have witnessed but one case of surgical septicæmia, and that in a case in which I had ligated the radial artery for a gun-shot wound of the deep palmar arch. The patient was considerably anæmic from frequent and repeated losses of blood. He afterward made a good recovery. I believe, also, that puerperal septicæmia is rare. I might add more cases in support of what I believe to be the reason of this rapid healing of wounds in these localities. I believe that, by certain natural conditions of our atmosphere, it is rendered to some extent antiseptic, or at least unfavorable to the existence and development of bacteria and other septic germs. It is a fact well known that fresh meat, cut and dried in the hot sun, cures without becoming tainted. This "jerked" meat enters largely into the summer diet of many of the inhabitants of this country who live away from the markets. It is said that the spores of the microbe are so universally distributed through air, earth, and water, that their exclusion from the human body is almost impossible. Moisture and warmth are conditions favorable to their growth and development. They require a moist surrounding in order to multiply, and, after removal of these conditions which favor their growth, their spores are carried through the atmosphere and thus contaminate the human body. Beale says (Microscope in Medicine) in a dry atmosphere the living bacterium would soon shrivel up and its life would be destroyed, it, as a living body, containing a large amount of water. On the other hand, the germs of bacteria may exist in countless multitudes in the atmosphere, and these under favorable circumstances will germinate and the resulting bacteria grow and multiply. Further, we know that a moist medium is required for the culture of these microbes and bacteria.

In these elevated regions the atmosphere is extremely dry, and this furnishes an unfavorable soil for the existence or development of such germs. The earth in these localities is also warm and very dry. There are probably not more than ten days in a year in which the ground is continually moist; in fact, we have dust about all the year, and we are frequently reminded of that fact by the violent winds that carry it into our houses and everywhere. If it is possible for the spores of these microbes to exist in our atmosphere, I believe our constant currents of air and our frequent winds are sufficient to drive them over our vast areas of mountains and valleys, and they are thus deposited in a barren soil. I have seen wounds, both in the human and the lower animals, heal under the most filthy conditions; and, if the bacteriologist could but get a look or a smell at one of our native Indian camps, he would stand in amazement when told that *their* wounds heal favorably under such conditions and habits. There is, beyond a doubt, something in our climate that is favorable to the healing of wounds, and I believe it to be our dry rare atmosphere, our dewless cold nights, our perpetual sunshine, and the constant currents of air which pass through our mountains and valleys. I am trying to solve some of these problems with the aid of the microscope, and hope to succeed.

—A man named Johnson, of Providence, recently swallowed sufficient strychnine to kill 200 men, after which he informed his wife of his action. She hurriedly emptied the contents of a can of kerosene down his throat and then summoned a physician. The latter thinks Johnson will recover.

SUGGESTION AND EXPECTANCY.

BY WILLIAM M. CAPP, M.D.,
PHILADELPHIA.

In an article by Dr. Dewees, on Amenorrhœa, etc., in THE MEDICAL AND SURGICAL REPORTER of June 30, 1888, he speaks of the ecbolic effects of manganese in two cases which he details. In seeking to account for the action of the drug in these two cases, he overlooks the most important considerations of all—namely, those which just now are occupying the minds of many of the French faculty—suggestion and expectancy. The patients applied to him with a well-formed but concealed purpose, representing, however, that they sought simply for a restoration of the catamenia (under proper circumstances, as they alleged). They believed that he could accomplish it, were determined upon having it, and probably covertly assisted in its production. They knew enough to see that their ulterior object would be gained if their ostensible object were accomplished. Here was a chance for the exercise of the force of mind over matter, of a most favorable kind, and the expected effect was accomplished presumably to the patient's satisfaction. The doctor, however, played only a subordinate part. He did nothing consciously or directly to produce the effect obtained; indirectly, however, and unconsciously, he inspired the patients to believe that his management in the matter would result as they suggested to themselves, expected, and fully determined that it should. Hence the result narrated, which was not from the physiological action of the drug used.

Recently a case somewhat similar in its main features came under the writer's observation. An unmarried woman below the age of twenty came under care for a hemorrhage. A little investigation showed it to be the sequel to an abortion. She frankly enough did not claim to have been deceived, since she had followed her own inclinations. She had applied to a physician much older than herself, in a matter of sort way, stated the condition of things without reserve, and asked relief. Her manner and conversation implied that she thought she was doing no unusual thing. She stated that he appeared to sympathize with her in her trouble, and gave her a prescription for pills which would "*make it all right.*" In a few days, after some little pain, a fœtus of about two months came away, hence the hemorrhage on account of which application was made on her behalf to the dispensary for a doctor's aid. Care was taken to look the matter up, and it was found that the physician had given a placebo with the assurance as stated, and in the drug-store the recipe on file showed that the pills contained simply a small amount of sulphate of cinchona. The dose was, of course, inert for such a purpose. The girl was a simple-minded creature of defective training and loose surroundings, and appeared to be unconscious of having done differently from others. But she had implicit faith in the physician, who, she thought, had promised to aid her to accomplish a certain purpose, and a full expectation and determination that it should be accomplished. A careful inquiry seemed fairly to place the case in the list of those properly known as effects of mind over the body.

GALVANO-CAUTERY ELECTRODES.

BALDWIN GLEASON, M.D.,
PHILADELPHIA.

A few weeks ago, my attention was attracted by an article in the *Medical News*, by a Dakota physician, describing how a practical galvanic battery might be made at a cost of five dollars. Galvano-cautery knives that will be more useful than any to be had in the market can also be made at home at a trifling expense.

Select copper wire of sufficient diameter (No. 14 will do) so that it will not heat during the passage of the electric current, yet not so large as to take up too much room when the electrode is used through a nasal speculum. Cut the wire into lengths of about six inches. Get a jeweler to drill a hole in one end of each length, for the reception of the platinum loop, and bend the other end so that, when two lengths are bound together with silk, they will fit into the handle of the electrode. Such copper wires, already drilled and bent, can be bought at surgical instrument stores in this city for fifty cents a pair. Holding a pair of such wires by their drilled ends, bind them firmly together by figure-of-eight turns of ordinary black button-hole silk, being careful that each turn lies smooth and tight on and between the wires before the next is put on. When the bent ends of the wires are reached, fasten the ends of the silk by a few half-hitches. The copper wires are now ready to receive the platinum tip. Buy, at any dental supply store, some

platinum wire. This should not be too thick, or it will not heat up readily, not having sufficient resistance; nor too thin, as in that case it will bend when you attempt to press it into the tissues. No. 22 is the size generally used. Bend a piece one and a half inches long sharply upon itself, and insert the ends into the holes drilled in the copper wires. Clamp the copper firmly on the platinum with pliers, and your cautery-knife is made.

Most of the cautery-knives for sale have the platinum soldered to the copper. This a disadvantage, as they easily break at that point, necessitating frequent resoldering. Clamping the copper about the platinum

does away with this disadvantage, while a few strokes with a file make a smooth joint. A coat of shellac varnish may be put upon the silk covering the copper wires, to improve the appearance of the electrode. Before attaching the platinum loop to the copper, it may be made to assume any desired shape by a few blows from a hammer. An ordinary tack-hammer and flat-iron will answer the purpose of hammer and anvil, if one has nothing better at hand. A very convenient electrode for anterior hypertrophies in the nose is made by hammering one side of the bent platinum wire flat and leaving the other round. Hammering increases the resistance; so that the flat side of the wire will heat up more quickly than the round, and there is no danger of singeing the septum when such a knife is used. When it is desired to make a puncture rather than a cut, or cut only with the point of the knife, the platinum wire should be left nearly round, and only the very end or bent portion hammered. Then only the very end may be made red-hot. Such electrodes are convenient for cauterizing the middle turbinated bones or hypertrophied tonsils.

Galvano-cautery knives, such as described, are used in the Nose and Throat Dispensary of the University Hospital and in the private practice of Dr. Carl Seiler, by whom they were devised, and also in my own. A physician can make them with platinum tips of many shapes and sizes, that will heat up at the exact part desired, and will find them more practical than those for sale, while their cost in money is almost nothing.

1346 Spruce Street.

Society Reports.

AMERICAN OTOLOGICAL SOCIETY.

TWENTY-FIRST ANNUAL MEETING, AT NEW LONDON, CONN., JULY 17, 1888.

MORNING SESSION.

The Society was called to order by the President, Dr. J. S. Prout, Brooklyn, who alluded in his opening address to the loss sustained by the Society in the death of Dr. C. R. Agnew, of New York, and suggested that action be taken.

On motion, Dr. Gorham Bacon and Dr. W. H. Carmalt were appointed to prepare an appropriate minute on the subject.

Drs. Green, Theobald, and Carmalt were appointed as the Business Committee.

Dr. E. Williams, of Cincinnati, on account of failing health, presented his resignation. This was accepted, and, on motion of Dr. Carmalt, the by-laws were suspended, and Dr. E. Williams was elected an honorary member of the Society.

Dr. W. H. Carmalt presented the report of the Committee of Conference on the Congress of American Physicians and Surgeons.

The report was accepted, and it was decided that, when the Society adjourns, it adjourn to meet at the Arlington Hotel, Washington, D. C., September 18, 1888, at 11 A.M.

On motion of Dr. Green, it was decided that the meeting should be strictly for scientific matters, and should not be regarded as

a business meeting, and that it should not take the place of the annual meeting.

The reading of papers was then taken up. Dr. S. Sexton, New York, read by title a paper on

Periostitis Externa of the Mastoid

and one on

Some of the Indications for Excision of the Drumhead and Malleus.

Dr. C. H. Burnett, of Philadelphia, read a paper on a

Case of Aural Vertigo (Menière's disease)

which was relieved by excision of the membrana tympani and malleus.

The patient was a young unmarried woman, 37 years of age, who six years previous had been under treatment for chronic naso-pharyngeal catarrh and chronic catarrh of the left middle ear, accompanied with difficulty of hearing, tinnitus aurium, and a sense of fulness in the affected organ. Treatment of the catarrhal disease of the ear produced no benefit. After the lapse of six years, the symptoms already named grew worse, and there was superadded marked aural vertigo. The membrana tympani in the line of the malleus-handle was found adherent to the promontory, and the consequent retraction of the entire chain of bones was held to be the cause of the aural vertigo and of the sense of fulness and of the tinnitus.

The operation of excision of the membrana tympani and the malleus was performed under ether May 21 last, with entire and immediate relief to the aural vertigo (which before had often been sufficient to cause the patient to hold to a lamp-post for support), and to the sense of pressure and tinnitus, which good result has been maintained to the present time. The hearing was practically unaffected by the operation. The incus was detached from the stapes, but could not be removed, as it slipped into the attic, and grappling for it is not advisable on account of the risk of irritation. Its removal, furthermore, would have no effect in the result of the operation.

Dr. J. O. Tansley, New York, in opening the discussion, said: I have now under my observation a girl on whom this operation was performed some eighteen months ago. When she came to me, the whole internal canal was filled with polypi, and she presented serious brain-symptoms. I took out all the polypi and found a portion of the drum remaining, and above a localized necrosis, into which a probe passed at least one-fourth of an inch. The patient has been under observation every day for two months. The local necrosis is healed and she is doing well. There are still some brain-symptoms. It seems to me that this is a very serious operation, and I should hesitate some time before performing it. In this case the result seems directly traceable to the operation.

Dr. C. H. Burnett, Philadelphia: My patient did not remain in Philadelphia, but I was informed that, two or three weeks after I saw her, a discharge appeared. I think that there is still a slight discharge, but the membrane is forming. In another case a slight discharge appeared soon after the operation, but ceased after the membrane had reformed. The case reported by the last speaker was not one of the class to which I have alluded. The operation was evidently not properly performed, if there remained a portion of the membrane and there was necrosis. I have not found this a dangerous operation. No one has reported bad results from this operation, properly performed.

Dr. Chas. J. Kipp, Newark: This operation has been performed a number of times by a foreign operator for the relief of tinnitus and vertigo, but he has given it up because it did not relieve these symptoms satisfactorily. He, however, did not have any bad results.

Dr. S. Sexton, New York: I have performed this operation between fifty and one hundred times in the past few years, and have obtained decided benefit in a number of cases of tinnitus and other subjective symptoms. I have known of no case in which there was aggravation. In many cases where there has been no marked tinnitus, the distressing sense of pressure has been overcome. The tinnitus is not always relieved by the operation. Dr. Burnett has referred to the closure of the drumhead. My principal endeavor has been to avoid reformation of the drum membrane. In a number of cases where this occurs the good hearing is lost. I have prevented this by the application of a solution of salicylic acid in ether to the margin of the closing membrane. This has succeeded even where the membrane has closed down to a minute opening. In regard to the purulent case to which allusion has been made, I have operated on a number, and, on the whole, they are the more satisfactory cases.

Dr. B. Alex. Randall, of Philadelphia, was invited to take part in the discussions of

the Society. He said: It may be that in Dr. Tansley's case the operation was done for the necrosis. The presence of polypi of the size referred to indicates great neglect, and the results are more probably attributable to this neglect than to the operation.

Dr. A. H. Buck, of New York, read a paper on

Reflex Influences in the Production of Naso-Pharyngeal Catarrh.

The object of the paper was to call attention to those comparatively remote exciting causes of naso-pharyngeal catarrh which act, so far as it is possible to explain their mechanism, through the intervention of the vaso-motor fibres of the sympathetic nerve. We know, he said, little of the direct exciting causes of naso-pharyngeal catarrh. The most common indirect cause is chilling of the surface of the body. According to certain authorities, affections of the teeth should rank next in order of frequency. The author had, however, seen very few cases in which dental disturbance played the part of a promoter of naso-pharyngeal catarrh or of aural disturbance. Some of those indirect causes which he had observed were then enumerated. Irritation of the gastro-intestinal canal is, in not a few instances, a strong exciting cause of naso-pharyngeal catarrh and of all the aural disturbances growing out of such a catarrh. A man, 45 years of age, had for years been more or less a sufferer from naso-pharyngeal catarrh, with tinnitus aurium and slight impairment of hearing; and, more recently, he had begun to suffer from feeble digestion. He noticed that after indulgence in certain articles there would be abdominal discomfort, and, at the same time, marked exacerbation of the naso-pharyngeal catarrh. So long as the offending substance was in the stomach, there was only a slight sense of discomfort; but, in the course of three or four hours, a slightly painful peristaltic movement would set up in the bowels, simultaneously the secretion from the vault of the pharynx would become unpleasantly active, and the tinnitus would increase. This condition would last for an hour, and then the naso-pharyngeal catarrh would return to its usual state. These attacks were accompanied with the escape of large quantities of gas by eructation. In many patients, usually men between 40 and 60 years of age, when we have reason to believe that the gastro-intestinal tract is habitually in a state of greater or less irritation, we find the faucial mucous membrane red and swollen. In these cases the disease which claims chief attention is the gastro-intestinal affection.

Reflex influence involving the vault of the pharynx and the ear may emanate from more distant sources. A woman, 40 years of age, complained of distressing tinnitus involving both ears. There had been mild naso-pharyngeal catarrh, from time to time, for many years. At times she was almost entirely free from tinnitus. I always, he said, succeeded in giving prompt relief by applying a moderately strong solution of silver nitrate, with a mop of absorbent cotton, to the vault of the pharynx. After a time these failed to give relief. It was then learned that for many years she had suffered with pain in the pelvic regions and back, and that at this particular time she was suffering in a more marked degree. A specialist was then consulted, and it was found that there were retroversion of the uterus and subacute parametritis. These conditions were removed and the tinnitus disappeared without treatment to the vault of the pharynx.

The author stated that he had spoken of these as indirect causes—that is, as factors competent to aggravate a pre-existing but perhaps latent catarrhal disease; but he saw no reason why these reflex influences might not in certain cases play the part of direct exciting causes. He considered it impossible to demonstrate the correctness of this belief, and therefore preferred to adopt the view which assigns to them a less independent *rôle*.

Dr. J. O. Tansley, New York, in opening the discussion, said: I meet with many cases of naso-pharyngeal catarrh in young girls, 15 to 20 years of age, who are decidedly anæmic and chlorotic, and who suffer with constipation. I have found that the latter is the cause of the catarrhal symptoms.

Dr. S. D. Risley, Philadelphia: It is pretty generally admitted that nasal and pharyngeal diseases are especially liable to occur in persons of a gouty diathesis. Naso-pharyngeal disease is one of the most uniform manifestations of lithæmia. In regard to the symptoms detailed in the first case of Dr. Buck, I should suggest that the digestive disturbance was probably associated with a lithæmic condition.

Dr. C. H. Burnett, Philadelphia: I have seen a number of cases of tinnitus without deafness, due entirely to dyspepsia. The use of nitrate of silver has been referred to. While this may be of service in other locations, I think that it is the worst application that can be made to the nose or the naso-pharynx. Its use will be followed

sooner or later by sclerosis and atrophy. It will apparently cure a hypertrophic catarrh, but the case comes to the rhinologist later, with a marked atrophic process in the mucous membrane. I have entirely abandoned the use of nitrate of silver in affections of the nares.

Dr. S. Sexton, New York: I have seen many cases in which irritation in the mouth has been the cause of naso-pharyngeal catarrh and aural symptoms. A woman was brought to me with intense pain in the ear and the head. There was nothing in the condition of the ear to account for these symptoms. Examination of the mouth showed that she was wearing a plate to bring the teeth closer together. The gum was intensely inflamed, although the patient complained of no discomfort. The removal of the plate caused a disappearance of the pain in the ear and head. I have seen many such cases.

Dr. J. O. Tansley, New York: I have seen many cases in which irritation of the teeth caused aural symptoms. I agree with Dr. Burnett that nitrate of silver should not be used in the nasal cavity. I have not made such an application for a number of years. There is in catarrh an increased thickening of the basement membrane; this tends to contraction, and the tendency to contraction is increased by the use of nitrate of silver. I employ such agents as induce an exosmosis.

Dr. J. F. Noyes, Detroit: This paper brings up the fact that it is important that in our special practice we should consider general practice. I have always recognized these so-called reflex causes, and have treated cases by searching out these causes. A remarkable case came under my notice, in which a woman after confinement developed naso-pharyngeal catarrh. There was profuse secretion. The trouble continued for a year in spite of treatment. Finally she passed into the hands of a gynecologist. The cause was then discovered, and treatment of the uterine disease cured the naso-pharyngeal disease.

Dr. Samuel Theobald, Baltimore: I think that where atrophy follows hypertrophic catarrh it is the result not of the application of nitrate of silver, but of the the continuance of the catarrh. I question whether solution of nitrate of silver, ten to fifteen grains to the ounce, will produce sloughing. I regard this agent as a valuable application in disease of the nasal membrane.

Dr. Chas. J. Kipp, Newark: I agree with Dr. Theobald as to the value of nitrate of silver. I rarely use it in a stronger solution than twenty grains to the ounce, and neutralize it afterward with salt water.

Dr. Henry D. Noyes, New York: I have frequently noticed the connection between the lithæmic condition and certain affections, not only of the naso-pharynx, but also of the external auditory canal. There are certain eczematous conditions associated with the gouty diathesis.

Dr. F. P. Capron, Providence: I have seen a number of cases of so-called hay-fever in which the premonitory symptoms were those of indigestion. For two or three weeks before the time of the onset of the regular attack, the patient would complain of digestive disturbance.

Dr. Huntington Richards, of New York, read a paper on a case of

Polypoid Angioma of the Ear.

The patient, a girl 6 years of age, came under observation May 4, 1888, with profuse fetid otorrhœa, unaccompanied with pain, and dating only from the preceding February. Hearing seemed good. No bleeding from the ear had ever been observed. The general health was excellent.

Examination of the affected ear revealed a polypoid mass, almost occluding the canal. The color was deep purplish-red. A considerable portion of the tumor was at once removed with the snare, and the remainder of the growth was extracted on the following day, leaving a small pedicle attached, seemingly to the outer surface of the drum membrane, close to the prominence formed by the short process of the hammer. This stump was cauterized with chromic acid. Hemorrhage from the cut surface of the growth was unusually profuse at both operations. The child's hearing is now excellent, although both membranes are depressed and of a dark grayish-red color. The removed growth was pronounced to be an angioma. Three micro-photographs, showing the appearance of the growth, were exhibited.

Dr. Huntington Richards, of New York, reported a case of

False Drum Membrane.

The patient, a man 21 years of age, was totally deaf in the affected ear. There was a vague history of an attack of otitis media in early childhood. The other ear presented the common appearance of otitis media purulenta chronica. Examination of the ear that was not discharging showed a mem-

brane occluding the canal. It differed from the normal drum membrane in color, shape, relation of its plane to the long axis of the canal, and in apparent thickness. It varied little in color from the skin lining the canal. The surface was perfectly smooth.

A triangular opening was made through this membrane. The operation caused no pain. Through this opening, it was seen that there was no drum membrane, but that the inner wall of the tympanic cavity came into view. The hearing was only slightly improved. When seen a few days later, no discharge had appeared. Since that time he has not returned to the infirmary.

Dr. S. Sexton, New York, in opening the discussion, said: I have seen several such cases as that described in the last paper. In one seen last year, I removed the membrane, and then took out the malleus and incus. This case made a good recovery. The improvement in hearing was decided. I would suggest this operation, in such cases, as a possible means of improving the hearing, for it opens up the tympanic cavity, which is a good condenser of sound; and, in the second place, to prevent the accidental occurrence of inflammation in these parts when it might be difficult to obtain relief.

Dr. T. Y. Sutphen, Newark: I have seen one or two cases of this trouble, which seems to me to be due to cicatricial closure of the external canal. It seems to me that the condition would be best spoken of as cicatricial closure of the canal.

Dr. Chas J. Kipp, Newark: These cases result from granulations, and I have watched the formation of these membranes. In treating this condition, I have incised the membrane and put in laminaria bougies, and the false membrane has disappeared.

Dr. A. Mathewson, Brooklyn: A woman was under my care for some time with an eczematous condition of the external meatus. She then passed from observation. Some time later she presented herself, with a disk-like closure of the external canal. This was not complete, but there was a small opening in the centre. I dilated this opening with laminaria bougies, and the ear was left in perfect condition.

Dr. Samuel Theobald, Baltimore: The members may recall a case that I reported in which there was occlusion of both external canals. There was a history of suppuration, and no doubt there was ulceration and gradual closure.

Dr. Chas. H. Burnett, Philadelphia: I have seen several of these cases of dermoid diaphragms in the canal. Three of these were in private practice. One was in an old man, and it remained imperforate during the whole time he was under observation. The other cases were perforate when they came to me. There was slight discharge, which I checked, and the perforation healed. In one case the discharge returned after a short time, and the perforation reappeared. Under treatment it healed, and I have reason to believe has remained closed since—a period of four or five years. In the other case it remained closed for a year, when the opening reappeared with slight discharge. The discharge ceased under treatment, and the opening closed and has remained closed.

Dr. B. Alexander Randall, Philadelphia: In the case of a boy, 12 years old, in which there was closure of the meatus as a result of injury with forceps during labor, I excised the diaphragm. The cavity was thoroughly washed out. The case was then treated in the ordinary way. The hearing obtained was certainly one-fourth of the normal.

EVENING SESSION.

Dr. J. B. Emerson, of New York, read a paper on

The Flexible Catheter as a Drainage-Tube,

and cited several cases exhibiting the use of the flexible catheter as a drainage-tube. He said that with deep-seated inflammation of the auditory canal or mastoid cells, maintenance of drainage through a fistula is a necessity, and to prevent closure of the fistula, either by granular growth or natural healing, is important. Dr. Emerson recommends the use of the flexible catheter as generally the best means to employ, and states his reasons to be the comparative comfort and safety, together with convenience of control by both surgeon and patient. The efficiency observed in the use of the flexible catheter was also referred to.

Dr. O. D. Pomeroy, New York, in opening the discussion, said: Some years ago I recommended the use of soft rubber tube in suppurative otitis in little children with closure of the canal with no changes except swelling. The canals are so small that the tube cannot be pushed in in the ordinary manner. A piece of small tubing was hooked to the extremity of a notched probe, which passed through it. The tube was then drawn tight, thus reducing its size. In this way it could be readily introduced. When the tube was released it tended to resume its proper size, and the probe was withdrawn. Almost all these cases did well.

Dr. Chas. J. Kipp, of Newark, reported three cases of

Transient Bilateral Horizontal Nystagmus in connection with Purulent Inflammation of the Middle Ear.

Case I.—A young man, 21 years of age, had had otorrhœa seven or eight years previously. Three months before coming under observation he had an acute exacerbation and suffered intensely with pain in the ear and head. The otorrhœa much diminished. Two or three weeks later he came, stating that he saw objects double, was dizzy, and could not walk. There was marked nystagmus in a horizontal direction. The vertigo and nystagmus continued four days. With the cessation of the nystagmus the vertigo disappeared.

Case II.—A young man, treated six years previously for acute otitis media purulenta ending in recovery, appeared in March with an acute attack. Paracentesis was performed. The pain, however, continued for a long time. Finally swelling developed behind the mastoid, and this was accompanied with several epileptiform attacks. One day, pressing on the swelling, pus poured from the canal. With this there was a sudden jerk of the head and nystagmus. The latter continued for about ten minutes. This was produced every time pressure was made on the mastoid. The mastoid was subsequently opened. Since then there has been improvement.

Case III.—A young man, after exposure, was seized with intense pain in the ear, followed by otorrhœa. When he came under observation there was great pain. This was not relieved by treatment, but continued two or three weeks. Then a swelling appeared below the ear. This was incised and a large quantity of pus evacuated, with relief to the pain. Some days later, while washing out the cavity, the fluid came through the ear when considerable force was used. At the same time there was a jerk of the head and nystagmus continuing several minutes. This could always be produced by making a forcible injection.

Dr. O. D. Pomeroy, New York, in opening the discussion, said: Reference has been made to epileptiform symptoms in one of the cases. I have recently seen a case of epilepsy in which the exciting cause was suppuration of the middle ear. With recovery from the ear-disease, the convulsions ceased and have not returned.

Dr. J. O. Tansley, of New York, exhibited

An Improved Aural Snare.

The snare was devised to overcome the objection to the ordinary Wild snare, which is the little jerk and rebound of the instrument when the growth is cut through. The instrument exhibited consists of a small tube through which the wire passes, to be connected with a small bobbin, by the turning of which it is gradually shortened.

A paper by Dr. S. Sexton, New York, on

Foreign Bodies in the External Auditory Canal

was read by title.

The Society then went into executive session, and the following officers were elected:

President, Dr. J. S. Prout, of Brooklyn; *Vice-President*, Dr. Gorham Bacon, New York; *Secretary and Treasurer*, Dr. J. J. B. Vermyne, New Bedford, Mass.; *Committee on Membership*, Dr. A. Matthewson, Dr. D. B. St. John Roosa, and Dr. John Green; *Delegate to Congress of American Physicians and Surgeons*, Dr. W. H. Carmalt, New Haven; Alternate, Dr. G. Bacon, New York.

The Society then adjourned to meet at the Arlington Hotel, Washington, D. C., Tuesday, Sept. 18, 1888.

Periscope.

Case of Sextuple Pregnancy.

An extraordinary case of multiple pregnancy recently occurred at Castagnola, near Lugano, in Switzerland. A woman, 36 years old, wife of the local *sindaco*, was delivered on May 4, of six children—four boys and two girls—at a birth. They were born alive, though prematurely, but they all died in a few seconds. Their united weight was only three pounds thirteen ounces, and the length of their bodies, which were perfectly well formed, varied from 8¾ to 10¼ inches. The case, which is said to beat all previous *authentic* records of human fecundity, is vouched for by Dr. Francesco Vassalli, of Lugano, who attended professionally on the occasion, assisted by Drs. Bianchi, Reali, and Solari, of the same place. Dr. Vassalli has reported the case in detail in the *Gazzetta Medica Italiana-Lombardia* of June 2, and an abstract of his account may be interesting. It has been stated that the woman had previously borne seven children, in two batches of four and three respectively, but this is inaccurate. She was married only two years ago to a

widower, 41 years old, who had ten children by his first wife. There were no twins among these, but it appears that he has five cousins—brothers—each of whom is the father of twins. A sister of the patient has also borne twins on one occasion. The patient herself, in the first year of her marriage, had a boy who is now fifteen months old and in perfect health; she suckled him for eleven months, when she became aware that she was again pregnant. The catamenia had reappeared in the seventh month of her nursing, and the last period began on December 4 and lasted six or seven days; conception must therefore have taken place in the early part of January. The patient suffered severely almost from the first from weakness of the legs and vomiting, and in the fourth month the abdomen was as large as it usually is at full term. On the morning of May 4 (being about the 115th day of pregnancy), whilst doing some light outdoor work, she felt a sudden desire to empty her bowels, and, on squatting down for the purpose, there was a gush of hot liquid from the vagina, which she recognized as amniotic fluid. She immediately went home, walking with much difficulty, on account of something which she felt protruding from the vulva. A neighbor was called in, who found a tiny fœtus hanging by the foot, which was speedily delivered. All this occurred within a few minutes. Dr. Vassalli was then summoned, and found the os only partially dilated, whilst an unruptured sac could be felt through it. There being no urgent symptoms, the patient was kept quiet, and, after passing a fairly good night, she got up the next morning to attend to her household duties, feeling quite well. Toward mid-day, pains came on with increasing violence, and she lost a good deal of blood. Seeing that abortion was inevitable, Dr. Vassalli thought it advisable to hasten delivery. He therefore punctured the membranes and extracted a small fœtus by the foot. After tying the cord, he followed up the placental end with his right hand till he came to another sac of fluid; this he also punctured, and delivered a third fœtus. Two more were extracted in the same way, the whole procedure occupying two hours. Fresh hemorrhage now occurred, and the uterus did not contract. Dr. Vassalli therefore tied all the cords together and made gentle traction, at the same time applying pressure to the womb. This failing, he introduced his hand into the uterus and tried to bring away the placenta, which, however, he only succeeded in tearing, with the result of making the bleeding more alarming. Having no hæmostatics at hand, he sent for assistance, keeping his hand in the uterus meanwhile as a plug. It was four hours before help arrived; the after-birth was then got away with some difficulty, a sixth fœtus, enveloped in its own membranes, being found attached to it. The patient bore the trying ordeal very well, and made a good recovery. The heads of the fœtuses were rather large relatively to the bodies, and the eyes were covered with the pupillary membrane. The genital organs were completely differentiated. There was only one placenta. The specimen has been placed in the museum of the R. Scuola Ostetrica, at Milan. Dr. Vassalli calls attention to the curious fact that Castagnola is rather remarkable for multiple births. From the official registers, it appears that in a population of 585, from January 1, 1876, to May 10, 1888—that is, 13 years and 4 months—there was a total of 247 births. Of these, 228 were single and 19 multiple, the latter consisting of 5 cases of twins, 1 of triplets, and the present one of *sextuplets*. The proportion of twin births, therefore, was 1 in 45, instead of Schröder's estimate of 1 in 89; and of triplets, 1 in 228, instead of 1 in 7,910.—*British Med. Journal*, June 9, 1888.

Double Gun-shot Wound of Brain; Trephining; Recovery.

Dr. George R. Fowler, Surgeon to St. Mary's Hospital, reported this case to the Brooklyn Surgical Society, February 2, 1888: The patient, a man 30 years old, entered St. Mary's Hospital May 13, with a gun-shot wound of the head. The pistol was fired at short range, the muzzle almost touching his forehead. The first bullet entered the frontal bone a little to the left of the median line; the second entered at the inner canthus of the right eye, tearing away the lower and posterior portion of the frontal sinus of that side. He was unconscious when he came into the hospital. After making a crucial incision and laying bare the bone, it was found that a compound fracture of the frontal bone had been sustained, the bullet having passed directly downward, perforating the dura and being lost in the cerebrum. The bullet was from a 32-calibre revolver, and the opening in the dura was about the size of a little finger. Some portion of the frontal bone, which was driven into the brain, was removed with the forceps, and was found to be stained with the lead of the bullet.

It was difficult to trace the course of the

second bullet, but the posterior wall of the right frontal sinus was entirely destroyed, and portions of that were also taken out from the cerebrum. A portion of brain-matter escaped. The portion of the frontal lobe resting on the roof of the orbit of this side was destroyed. There was a considerable laceration of the brain at this point. After removing the débris, Dr. Fowler tried to locate the balls by drawing an imaginary line across, as nearly as possible, in a line with the pistol, and trephining posteriorally at a point where that line would meet. After trephining the occipital bone, a slender needle was passed into the brain substance, making the needle pass systematically in lines radiating from this latter opening as a central point to all portions of the brain as nearly as could be reached, but no trace of the bullet could be discovered. The openings were then closed.

In front, after removing the débris, about a dozen strands of catgut were passed into the wound, coming through the frontal bone, or rather through the tissues covering the frontal bone; and half a dozen strands of catgut were also passed down through what remained of the frontal sinus to afford an escape at this point. The left nasal cavity was irrigated with mercuric iodide solution, cleansed and stuffed with iodoform cotton, and antiseptic dressing applied. The patient's after-history was entirely uneventful. He never even complained of a headache. He was up and about, assisting in the wards of the hospital as a ward orderly, in three weeks, and left the hospital June 7, fully healed and in possession of all his faculties. There is a little difference between the pupils of the two sides, the left being comparatively larger than the right. This is the only indication of any disturbance, if, indeed, this is due to the injury.

About the 5th of last September he noticed some discharge where the upper opening had been, and upon exploration necrosed bone was found, which could be discovered from both openings. The parts were reopened, a small portion of the bone was removed from the lower opening, and it was thought that that would end the trouble. But it did not, and about four weeks afterward he again appeared with the upper opening still discharging pus. Another exploration revealed the existence of necrosed bone. A long incision was then made, connecting the two openings, from the central portion of the frontal bone down to the site of the old wound and to the inner canthus of the left eye. A sequestrum, three-eighths of an inch in length, was found after chiseling away a part of the frontal bone. There was also found lying at that point a strong fibrous partition between the fragments of bone and the cavity of the skull beyond, showing that nature had walled out, as it were, this portion of necrotic bone and left it lying there loose. It was removed, catgut drains were placed in position, and the patient made a rapid and complete recovery. He suffered —at the time of the report—from nothing except, perhaps, a little mental depression, which may or may not be the result of the original injury. Dr. Arthur Mathewson examined him and stated that the difference in the pupils was probably a congenital defect, and had nothing to do with the injury. Both bullets are still somewhere in the brain. Dr. Fowler has made no attempt to locate them with the induction balance. This case is an example of the toleration of the brain-tissue to the infliction of considerable traumatism, and to the presence of foreign bodies.

Dr. Wight, in opening the discussion on Dr. Fowler's communication, said that in 1864, on board the hospital transport "Western Metropolis," he saw a man sitting in a chair with a hole right in the middle of his forehead, about an inch and a half above his eyebrows. The surgeon in charge had an excellent probe and was trying to get it into the hole. As Dr. Wight came up, he was handed the probe. He saw there was no hole in the skull, and learned that it was a pistol-bullet, which had been fired at a distance of not more than ten or a dozen feet. He handed the probe back to the surgeon, and put his finger upon the back of the man's head and felt the bullet there. He simply made a little incision at that point, and the bullet dropped out.

In another case, some twelve years ago, he saw a boy eleven or twelve years of age, and inclined to hydrocephalus, who, on the 4th of July, while playing, with another boy, with a ten or twelve inch cannon, had a stone as large as the size of an almond shot into his head. It entered the skull just immediately above the groove for the right lateral sinus. Dr. Wight saw him on the 5th of July, and, after exploring it carefully, trephined, but could not find the stone. The boy lived some eight or ten years, and then finally died of tuberculosis of the lung. He made good progress in his studies, and was a bright, active, business lad. Whatever became of the stone he cannot tell.—*Brooklyn Medical Journal*, June, 1888.

THE
MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science,	**2.50**
Reporter and Compendium,	**6.00**
Physician's Daily Pocket Record,	**1.25**
Reporter and Pocket Record,	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

MEDICAL BULLETINS.

In a recent number of the *Nation*, attention is called, in a sharp editorial, to the modern practice of issuing what are called medical bulletins in regard to the condition of distinguished patients. The editor of the *Nation* adds his own condemnation to that of Miss Frances Power Cobbe, in a late number of the *Contemporary Review*, and both point out clearly some of the most objectionable features of the too detailed reports which are often sent out nowadays by medical men who are in attendance upon eminent or famous persons.

This practice is not confined to any one country, but it is sufficiently common in America to deserve notice. Within ten years, we have had, at short intervals, the details of the illness of a variety of persons exposed to the public gaze. Presidents, generals, actors, authors, and even criminals have furnished subjects for these reports, and the community has been imperfectly instructed in regard to matters of pulse, respiration, and temperature, which can do it no good, and in regard to excretions and discharges, which are nothing if not disgusting.

Some of the lay critics have intimated that the medical bulletins are intended or expected to act as an advertisement of the physicians or surgeons in attendance. This is a natural inference, although we are convinced that it does injustice to some of those who have issued them. Of course, in so far as the criticism is just, it exposes a very contemptible motive; but we may leave it to those who think it needs to be made prominent to urge it as they think best. If it were wholly unjust, there would still be much to be said against the medical bulletins of the present day.

No one who has carefully studied this matter can doubt that one effect of bringing the laity to the bedside of distinguished patients has been derogatory to the sanctity of illness, and has broken down the privacy which most sufferers long for; more than this, it has robbed dying men of the dignity which death usually confers, so that, to paraphrase what Miss Cobbe says, their last hours are not remembered as those of great and noble statesmen or soldiers, but as those of weak and wretched men. This is an evil which seems to us greater the more we reflect upon it.

Another evil due to the publicity given to the details of the sickness and treatment of distinguished patients is the comment excited in regard to the medical or surgical measures carried out by their medical attendants. The discussions in regard to the treatment of President Garfield had not faded from the public memory before the painful contentions in regard to the malady of Emperor Frederick of Germany came to increase distrust of medical acumen and surgical skill.

The most recent case in which medical bulletins have been conspicuous has carried the possibilities of evil in a new direction, for it has furnished an opportunity for the venders of a secret remedy most ingeniously to turn to their own account the credit due to a well-known and very simple restorative agent.

These are some of the evils for which the modern practice of issuing medical bulletins is responsible. They are beginning to attract attention from thoughtful men outside of the medical profession, and we may be sure that they will bring our profession into contempt, unless they be soon corrected. It may not be necessary to adopt the suggestion of the *Nation*, that the medical societies take the matter up and formulate rules to govern the preparation of reports of the progress of patients in whose welfare the world has a deep interest; but something must be done to strip them of the appearance of advertising and to purge them of details which are useless or offensive in their nature.

One thing our non-medical fellow-men ought at least to know, namely, that what they condemn is equally deprecated by the members of the medical profession, and that, while we regret the necessity for their criticism, we accept their rebuke and hope to be profited by it.

EARLY OVARIOTOMY.

The question of early ovariotomy is one of importance; and the greatly lessened mortality after ovariotomy in recent years is at least partly due to earlier operation. Dr. Sutton, in the REPORTER, June 2, 1888, forcibly insists upon this point; but, from the illustrative case which he reports, it might be inferred that the advantages consist in the ease and rapidity with which the operation can be done. A short operation unquestionably favors recovery, not only by the less amount of shock experienced, but by the smaller number of germs which gain access to the peritoneal cavity. Adhesions are much less apt to be encountered in cases operated upon early, than in those in which operation has been deferred.

But there are other and weighty reasons why ovariotomy should be done early. Many dangers and much suffering are thus avoided. Formerly, it was considered advisable to delay operation until the tumor became abdominal, until it reached the umbilicus, or until the general health became affected. The soundness of this opinion is no longer admitted. It was urged in favor of waiting, that thereby the tumor would come in relation with the abdominal wall, that the intestines would be displaced, and hence would be in less danger of injury from the knife of the operator; but, as the abdomen is opened daily for disease other than tumors, without injury to the intestines, the force of this argument is lost. It was urged with more reason that intra-abdominal manipulations are rendered easier in late operations, owing to the stretched condition of the abdominal walls; but experience in abdominal section for pelvic inflammations has largely removed the fear of tense recti muscles, and has demonstrated the comparative facility with which intra-pelvic manipulations can be made. The supposed greater difficulties in the technique of early operations no longer influence the surgeon.

The undoubted semi-malignancy of varieties of ovarian tumors, formerly considered benign, is a strong indication for early operation. A. Doran and others have repeatedly observed the development of malignant tumors in the abdomen after the extirpation of dermoid tumors. Numbers of cases of proliferating glandular cystoma have been reported in which, after ovariotomy, gelatinous masses formed in the abdominal cavity and adhered to a large part of the peritoneum—pseudo myxoma peritonei. In all these cases, the ovarian tumor contained tough gelatinous material, either mainly or exclusively. As is well known, papillary cystomata are very apt to infect the peritoneum and cause secondary

papillomata. This may occur spontaneously, either from the separation of papillary masses which become grafted upon the peritoneum, or by rupture of the cyst and diffusion of its contents throughout the peritoneal cavity; or infection may occur during ovariotomy. There seems to be very little doubt that the peritoneum may serve for the implantation and further growth of particles of all kinds of ovarian tumors, and that this is especially apt to happen, apart from malignant growths, in papillary cystomata and proliferating cysts with thick non-fluid contents. Were not the operation of tapping ovarian cysts already condemned or at least restricted to very exceptional cases for other sufficient reasons, this danger of infecting the peritoneum and causing secondary tumors might be urged against it. Early ovariotomy not only prevents the breaking-down of the general health which is always caused by long-standing ovarian tumors, but saves the woman from dangerous intercurrent accidents and diseases which at any time in the history of these growths are apt to occur. Torsion of the pedicle probably occurs in eight per cent. of all cases, and is especially common in dermoid tumors and tumors with long small pedicles. Hemorrhage into the cyst, at times rapidly fatal; gangrene or suppuration of the tumor, with acute diffuse peritonitis are the usual results of this accident, and, since the abandonment of tapping, are seldom met with from any other cause. Rupture of ovarian tumors has been repeatedly observed, though it is not so common as rupture of broad ligament cysts. No reaction may follow, but peritonitis is common after rupture of dermoids, or colloid tumors if hemorrhage occurs; and metastatic tumors may develop, especially after rupture of papillary cysts.

Solid tumors of the ovary are almost always malignant, hence early removal offers the only hope of radical cure.

Intra-ligamentary cysts form an exception to the rule of early operation. Although many of these tumors are papillomatous, the extreme difficulty and danger of removing them early, while they are entirely intra-pelvic, are considered at the present time a contra-indication to operation; but, as great improvement in the technique of the removal of these growths has been made in the past few years, it is to be hoped that further progress will enable the surgeon to remove them with safety, if not with facility. As a further exception, it should be mentioned that not a few surgeons refuse to operate on intra-pelvic ovarian cysts, which grow slowly or not at all, without special indications.

GLYCERINE SUPPOSITORIES FOR CONSTIPATION.

We have already, in the Reporter, February 4, 1888, directed attention to the injection of small quantities of glycerine into the rectum as a means of overcoming constipation. This method, somewhat extensively employed in Germany, it is often by no means convenient to carry out, because few syringes are available for injecting such small doses as fifteen drops of any medicament. A better idea has been suggested, as pointed out in the Reporter, July 28, 1888, by Boas, in the *Deutsche med. Wochenschrift*, namely, that the glycerine be given in suppositories or capsules.

This method is simple, easy of execution, and is said to be very efficient. Just how the glycerine acts to produce a movement of the bowels is not clearly understood, but the testimony is practically unanimous that fifteen drops of pure glycerine introduced into the rectum will bring about a comfortable and satisfactory evacuation of the bowels.

With glycerine in plenty and drug-stores full of good capsules it ought to be easy for our readers to test the value of this method, which, if it is what it is claimed to be, must be very superior to the use of enemata or—in many cases—of purgative medicines given by the mouth.

A CROOKED WAY.

Our attention has been directed by one of our subscribers, a distinguished surgeon of this city, to a circular issued by a firm of instrument-makers, which bears the following notice: "Physicians sending their patients to us to have trusses fitted, or for elastic hosiery, will please send letter of introduction, that they may be *credited with the 25 per cent. discount allowed them.*"

This is such a manifest bid for trade, and becoming a party to it such a flagrant violation of the principles of the Code of Ethics, that we quite agree with our correspondent that it should receive the unqualified condemnation of all honorable physicians. Any such collusion as this circular intimates may exist between doctor and instrument-maker results in robbery of the patient, and is thoroughly dishonest.

PRECOCIOUS MENSTRUATION.

A curious example of precocious menstruation, to which we briefly alluded in the REPORTER, August 4, 1888, is given by Dr. H. Kornfeld in the *Centralblatt für Gynækologie*, No. 19, 1888. The subject was a child only three years old, addicted to masturbation, which had a periodical flow of blood from the vulvar orifice in the beginning of April, May, June, and July, exactly at the time when the mother menstruated. No injury of the vagina could be found to account for the bleeding.

This case is curious enough, although, like most others of a similar sort, it has no obvious scientific value. If the masturbation were energetic enough, it would not be remarkable that it should produce congestion too violent for the resistance of the delicate mucous membrane of the genitalia; but, if it were not very energetic, or if it were not exercised shortly before the appearance of the bleeding, the case would simply belong to the class of physiological curiosities which is more interesting than instructive.

Masturbation in children so young is not so rare as some may imagine. It is a singular fact that, in many children, the propensity to amuse themselves with manipulations of a portion of the body to which the hands naturally gravitate in sleep and in waking seems to be about as natural as to eat when food is brought near them. The youngest children will unblushingly handle their sexual organs in the presence of their elders, and often need patient care to prevent their forming a regular habit of masturbation.

It would be interesting to learn how often there has been a coincidence of this practice with precocious development of the signs of puberty, and whether the former gives rise to the latter, or *vice versâ*.

HIGHER MEDICAL EDUCATION.

The College of Physicians and Surgeons of New York has announced that it will receive no new students, except upon the basis of a three-years' course of study. This is a strong and courageous movement, which, we trust, will be crowned with success. One way to help it to succeed is for medical men who approve the plan of a full three-term curriculum to prefer schools which have adopted this plan to those which have not adopted it. Warm support from the members of the medical profession is deserved by medical schools which turn their backs on the pecuniary advantages of a low standard of medical education; and those who have at heart the best interests of the rising generation of physicians, as well as of the profession at large, ought to bear in mind the names of the schools which have decided to give their students the best preparation for the work which the present times can afford.

While on this subject, we would refer to an implied criticism on a medical school in Philadelphia, which was contained in an editorial in the REPORTER of June 30, 1888. At that time we said: "There are ways in which men who have not been studying three years in any medical school can get a degree from it."

This statement, though literally and

exactly true, was alluded to by one of our contemporaries as if it were unfair, and one of the professors in the school referred to, in a visit at this office, has made a personal explanation in regard to the matter. As our statement was made simply in the discharge of what we conceive to be our editorial duty, and not from mere prejudice, we are happy to be able to state now, on the authority mentioned above, that hereafter the Medico-Chirurgical College of Philadelphia will exact a three-years' course of study from all persons to whom it grants its degree, and no study in a preceptor's office will be counted as a part of this period.

We trust that the time is not far distant when all the medical schools of the United States will stand squarely on this basis, and when there shall be no way in which the degree of doctor of medicine can be obtained in this country except after three years of honest study. Heretofore this principle has too often been neglected or evaded; but we trust that both the neglect and the evasion will soon be things of the past, and thus the medical schools of the United States will, before long, occupy the position which they should in the eyes of the whole world.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE NATIONAL PHARMACOPŒIA OF UNOFFICINAL PREPARATIONS. First issue. By authority of the American Pharmaceutical Association. Large 8vo, pp. x, 176. Published by the American Pharmaceutical Association, 1888.

As the U. S. Pharmacopœia does not contain a large number of remedies which are frequently used by physicians, the American Pharmaceutical Association has done a most serviceable thing in gathering together in one book the formulæ of the most important of these omitted preparations, so that druggists everywhere may prepare them according to one standard. The preparations embodied in this book include a number which are largely known to the profession through the industry of certain manufacturing chemists. It is not likely that the knowledge how to prepare these drugs will materially interfere with the sale of those which have already secured a sale and established a reputation, but it is very desirable that medical men should know how they are made, and that all druggists should know how to prepare them in an emergency, or if it is not convenient for them to keep a supply on hand. The book is one which will be of great value to druggists, and it will certainly prove interesting and instructive to physicians who have the opportunity and inclination to study its pages.

A MANUAL OF THE MINOR GYNECOLOGICAL OPERATIONS. By J. Halliday Croom, M.D., F.R.C.P.E., Lecturer on Midwifery, etc., Edinburgh, Scotland. First American, from the second Edinburgh, edition. Revised and enlarged by Lewis S. McMurtry, A.M., M.D., formerly Professor of Anatomy in the Kentucky School of Medicine, etc., with numerous illustrations. Small 8vo, pp. 228. Philadelphia: Records, McMullin & Co., 1888.

This book contains a great deal of information in regard to the details of minor gynecological operations, among which, to our surprise, we find included those for vesico-vaginal fistula, incision of the cervix uteri, trachelorrhaphy, removal of fibroids, and laparotomy. This is giving much more than it promises; but the reader can hardly complain, because it is very well done. As a handy book of reference for medical students, and for practitioners who are unable to have and study the more systematic treatises on gynecology, it is a volume which is calculated to be of great service. It is clear and simple, and goes into many details which are not usually discussed in more pretentious works, but which often prove troublesome to those who have not had the advantage of preparing for their work in large and well-conducted clinics. The work of the author is excellently arranged and well carried out; and the work of the American editor makes the book better suited than when in its original shape to the needs of American medical men.

LESIONS OF THE VAGINA AND PELVIC FLOOR. By B. E. Hadra, M.D., Austin, Texas, with 83 illustrations. Small 8vo, pp. 329. Philadelphia: Records, McMullin & Co., 1888.

The author of this book states, in his preface, that it was originally intended to discuss malpositions of the "uro-genital system"—an unfortunately chosen term—which are called "descents or prolapse," but that, as the work of preparation progressed, he decided to include all gynecological injuries of the vagina and floor of the pelvis. The result has been a book which covers much ground of interest to the general practitioner, and which contains much sensible advice. In the main, the author's expressions are carefully worded, and he seems to have been especially on his guard against certain errors of statement which have long been found in works on gynecology. His views in regard to the mechanical principles involved in the structure of the different pelvic organs are sound, and his recommendations in regard to the treatment of the gynecological injuries discussed are trustworthy. His book is rather a very readable exposition of his own opinions than an elaborate treatise; but we believe it is calculated to be useful as well as interesting.

ESSAYS ON HYSTERIA, BRAIN-TUMOR, AND SOME OTHER CASES OF NERVOUS DISEASE. By Mary Putnam Jacobi, M.D. Large 8vo, pp. 216. New York: G. P. Putnam's Sons, 1888. Price $2.00.

This volume contains a collection of essays of different sorts, which have appeared at various times and in various places. The most considerable are those

named in the title; but the shorter essays are equally of great interest and value. The author is known as an unusually careful student and a clear writer, and, when dealing with such subjects as these essays treat of, she is at her best. The space which we can spare for our reviews does not permit us to point out, as we would like to, the admirable way in which she has studied the physiology of brain-tumors and aphasia, or the manifestations of hysteria, or the acumen she displays in a criticism on Dr. Bartholow's Cartwright Lectures on the "Antagonism between Medicines and between Remedies and Diseases"; but we can heartily commend to our readers a careful perusal of her work, which cannot fail to prove both interesting and profitable.

CORRESPONDENCE.

Introduction of Ether into Philadelphia Practice.

To the Editor.

Sir: The *Excerpta* from the Presidential Address of Dr. Levis, published in the Medical and Surgical Reporter for July 21, suggest a thought in regard to the introduction of ether among remedial means used in Philadelphia practice. It was during the first half of the medical course of the University of Pennsylvania for 1847-48, which I attended as a second-course student, that I first saw ether administered by inhalation for the purpose of benumbing pain during an operation. Dr. William E. Horner was the operator, and the ether was exhibited under his superintendence. Great circumspection was observed in the process, thirty or forty minutes being consumed in producing full anæsthesia. The result was all that could be desired. I understood this to be the first use of ether for this purpose in Philadelphia. True it is that, during this entire winter, whilst I was in close attendance upon the clinics in the Pennsylvania Hospital, conducted by Doctors Randolph and Peace, no anæsthetic was employed, although many capital operations were performed; neither was it again resorted to during the winter's course at the institution first named.

Enos T. Blackwell, M.D.

Cedarville, N. J.,
July 26, 1888.

Milk for Babies.

To the Editor.

Sir: Dr. E. A. Wood, in the Reporter of June 30, has given some good suggestions on "Preparation of Milk in Summer."

In an article I have recently written, I have contended that the basis of our judgment with regard to cow's milk is wrong, since what is furnished by the milk-trade is not milk as it should be, but is an old, altered, and unfit milk for the babies when it reaches our city homes. Just now I have a terribly diseased child fed on milk bought at the grocery. Now, it is a fact that such milk is likely to be the worst kind of all. A milk-man, who formerly supplied my family, told me that all the old milk—too old to furnish for families for table use—he sold at the grocery to be used in cooking. Many a time have I been called to sick children who had been fed on such milk, and who began to thrive when fed on milk directly from milk-men. Not all grocery milk is of this kind, but it is sufficiently common to be dangerous and to suggest careful inquiry.

When practicing in the country, we did not consider it any very great calamity for a child to be deprived of its mother's breast. The child's life was not greatly imperiled thereby; the greatest disadvantage was the trouble entailed upon the mother, who had to care for the child. I think the country feeding on whole cow's-milk, or warmed with a little hot water, as also the experience of Dr. Lynde, of this State, quite controvert the notion that the excess of curd in cow's milk is in itself particularly harmful. I do not see why the same principle does not apply here as to the use of baked beans with adults. Chemistry teaches us that there is great nourishing quality in beans and peas, but it also teaches that the human digestive organs can extract only a portion of that nourishment, the remaining portion going off in the feces. If it should be contended that beans were not wholesome, because the stomach could not fully digest them, we should be obliged to give up eating "Boston baked beans." Why may not nutritive elements be carried off as waste from a child's stomach just as well as innutritious substances, so long as the child does digest enough of them for its own nourishment? If the child thrives on cow's milk, and yet does digest only one-half of the curd element, why is it not just as well for the balance to go off as waste as that we should feed with something else that is innutritious in order to make bulk for the proper stimulation of bowel movements? I think we have been mistaken here, and have condemned cow's milk because it was not wholly digested, curd being found in the stools.

My condemnation of cow's milk is not in consequence of the amount of curd it contains, but because the milk itself is not gen-

erally fresh and pure when given, especially in our cities; and I see no way of getting cow's milk which is fit for an infant's use until special efforts are made to produce and supply milk especially for infant-feeding—and this wholly outside of the present milk-trade. Let milk-men supply as they do now for common family use, but let special farms near our cities produce milk from good cows, fed on proper food and drink and otherwise properly cared for, and let the milk be properly cooled and served to the families having infants, directly after each milking.

Yours truly, E. Chenery, M.D.
65 Chandler Street,
Boston, Mass.

Notes and Comments.

Cholera Infantum.

Dr. Louis Starr, Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania, in a communication to the *Medical Standard*, July, 1888, says:

The large and frequent watery evacuations characteristic of this disease are such a drain upon the system that it is of the first consequence to replace the waste by food and drink and at the same time check it by appropriate treatment. The irritability of the stomach is a formidable barrier to alimentation, nevertheless every effort must be made to give food in small quantities and at short intervals. Should the infant be at the breast, it may be allowed to nurse for a few minutes every half-hour or hour. If hand-fed, it may be given the foods suitable in entero-colitis or in chronic vomiting, in such quantities as can be retained and at intervals corresponding in frequency to the smallness of the amount. Bits of ice and water should be allowed freely, even though they be rejected as soon as swallowed.

To check the diarrhœa, opium and astringents are necessary. A very serviceable formula is the following:

℞ Liquor morphinæ sulphat. . . . . f℥ i
Acid sulphurici aromat. . . . . ♏ xxiv
Elix. curaçoæ . . . . . f℥ iv
Aquæ . . . . . q. s. ad f℥ iii
M. Sig. One teaspoonful every two hours for a child six months old.

With this, two drops of laudanum, suspended in two teaspoonfuls of starch-water, should be given by the rectum every three hours. Two or three times daily a mustard plaster, one part of mustard to five of flour, must be applied over the whole surface of the abdomen, long enough to redden the skin, and the whole body should be sponged several times a day, with water at a temperature of 95° F.

The clothing, diapers, and person must be kept perfectly clean, the sick-room must be as large and airy as can be commanded, and the infant must lie upon a bed and not be constantly nursed on the lap. If it is possible, the patient should be sent early to the seashore or country, as this affords by far the best chance for recovery. Failing in this, morning and evening airings in a coach, or daily steamboat excursions, must be resorted to.

Stimulants are needed from the first, to ward off prostration—from five to ten drops of whiskey in a teaspoonful of lime-water may be given every two or three hours at the age of six months.

When collapse sets in, the quantity of alcohol must be increased, and, if the stomach can bear it, a combination of stimulants is useful, as:

℞ Spir. frumenti . . . . . f℥ iv
Ammon. carbonatis . . . . . gr. xxiv
Syr. acaciæ . . . . . f℥ i
Aq. menthæ pip. . . . . q. s. ad f℥ iii
M. Sig. One teaspoonful p. r. n

The temperature must be maintained by hot flannel wraps and hot water-bottles, and the child be kept in a horizontal position and disturbed as little as may be. In this stage, astringents are still indicated, but opium must be used with great caution, or even discontinued entirely, when there are cerebral symptoms and semi-coma.

In the fortunate instances in which this plan is successful, it is still necessary to treat the succeeding diarrhœa, and to build up the general health by good food, tonics, and fresh air.

Gastrostomy.

Dr. Miles F. Porter, of Fort Wayne, Ind., reports in the *Journal of the Amer. Med. Association*, July 30, 1888, the details of a very interesting case in which he performed the operation of gastrostomy upon a young man, 19 years old, who had a stricture of the œsophagus in consequence of drinking some caustic liquid. The operation was conducted in two "times," the first comprising the opening of the abdomen and securing to the edges of the wound a portion of the stomach; the second consisted in making an opening into the stomach. Between these two steps of the operation, the patient had a violent attack of broncho-pneumonia, which at one time led his medical attendants to despair of his life.

A Long Fast.

The story comes from Racine, Wisconsin, that John Zacher, after an abstinence from food for fifty-three days, has at last been induced to eat. The cause of his fast, it is said, was a disagreement with his father, with whom he has since come to an understanding. The physicians of Racine say it is probable that he will recover his health. They do not look upon his fast as an absolutely genuine one, insisting that he must have taken substantial nourishment, because it would have been absolutely impossible for him to have lived so long. Those who have been with him constantly, however, say he has taken no nourishment for fifty-three days. This account of his fast may not be true, but it is interesting. Succi, the Italian faster, has certainly proved that man may do without food for a much longer period than has hitherto been supposed possible.

The Effect of the Phylloxera.

It has been recently announced by the British consul at La Rochelle, that since the failure of the vineyards from phylloxera, an imitation of claret is made there by steeping raisins and currants in water, and mixing the compound with cheap Spanish wine. In other districts of France, a spurious brandy is made from a mixture of beet-root and cheap German spirit. This is a curious commentary on the belief held not long since that Pasteur had saved the wine industry of France from the ravages of the phylloxera.

Cocaine-Lanoline.

Mr. C. J. Boyd Wallis, L.D.S., has pointed out the value of lanoline as a medium for the application of cocaine for dental purposes, and communicates the following formula to the *Journal of the British Dental Association:*

Cocaine hydrochlorate	Parts	5
Acid carbolic (pure)	"	5
Menthol	"	5
Eugenol	"	10
Lanoline	"	75
		100

The cocaine and menthol should be well triturated with the eugenol, the carbolic acid then added, and the trituration repeated; the whole may then be added to the lanoline and thoroughly well mixed. Double this strength may be employed for sensitive dentine.—*Chemist and Druggist*, July 7, 1888.

Care of the Weak-Minded.

At the sessions of the National Conference of Charities and Corrections, in Buffalo, New York, July 7, 1888, a paper was read by Dr. Isaac M. Kerlin, of the Pennsylvania State Asylum at Elwyn. He favored placing all weak-minded children of school age and women of child-bearing age in the asylums, where they could be mentally improved. The children, he said, could be made self-supporting in the industrial departments, while others received benefits from its custodial treatment.

Clinical Features of the Uric Acid Headache.

Haig, in *St. Bartholomew's Hospital Reports*, vol. xxiii, p. 201, defines this as a headache which recurs at intervals of three days to a week, or from that to one or several months, throughout a large number of years in the life of an individual. It lasts from twelve to twenty-four hours and then goes completely away until the end of the interval. The attacks are rendered less frequent and less severe by a diet poor in nitrogen. There is often a family history of headache or of gout, or both. The author has frequently found this headache associated with a large excretion of uric acid, and has noted that the administration of an acid will stop the excessive excretion of uric acid and remove the headache in one or one and a half hours. He reports several cases in full, together with a tabular arrangement of the principal features of interest. The headache is probably caused by the action of some poison in the blood (uric acid) on a nervous (vaso-motor) system especially sensitive in some parts of the cranial circulation. Strychnine is sometimes very useful in this headache, on account of its tonic action on the vaso-motor centre. Symptoms of gastro-intestinal derangement are notable by their absence. The tongue is clean, the bowels regular, food is well taken, the pulse is slow, and the temperature normal. This is in marked contrast to the frontal headache, furred tongue, fever, rapid pulse, and disgust of food, of real gastro-intestinal derangement. The sulpho-cyanide is usually in excess in these headaches occurring in gouty or rheumatic families, as Fenwick has remarked. The author then lays stress upon the alliance between these headaches and epilepsy, as illustrated by one of his cases, in which the two affections appeared to improve together under a proper diet.—*American Journal of the Medical Sciences*, July, 1888.

Glass Balls for Refilling Wine-Casks.

Wines which contain less than about fifteen per cent. of alcohol cannot be kept in casks, unless the latter are kept full and protected from the air. When a portion of the contents of a cask is withdrawn, the vintner fills it up again from reserved stock until the particular brand gives out. He then used to, and still does, resort to the practice of putting pebbles into the cask to occupy the volume of the displaced wine; but, even with the best of care, some ferruginous or otherwise impure pebbles are apt to get in, which may injure the flavor of the wine. For this reason, glass balls are now being used by many in place of the pebbles.—*American Druggist*, July, 1888.

Formula for Antifebrine.

Dr. I. N. Love (*Weekly Medical Review*, July 7, 1888) says that the following formula is a pleasant and convenient form of administering antifebrine:

℞ Antifebrine . . . . . ℈ij
Alcohol . . . . . f℥ij
Glycerine . . . . . f℥iij
Cinnamon water . . . . . f℥j
Simple syrup . . . . . f℥iij
M. Sig. One-half teaspoonful to two teaspoonfuls every two to four hours, according to age and necessities.

Examinations for Appointment in the Medical Corps of the U. S. Army.

An Army Medical Board will be convened in New York City, New York, October 1, 1888, for the examination of such persons as may be properly invited to present themselves before it as candidates for appointment in the Medical Corps of the Army.

Application for an invitation should be addressed to the Secretary of War, stating date and place of birth, place and State of permanent residence, and accompanied by certificates, based on personal acquaintance, from at least two persons of repute as to citizenship, character, and moral habits; testimonials as to professional standing, from the professors of the medical college from which the applicant graduated, are also desirable. The candidate must be between 21 and 28 years of age, and a graduate from a regular medical college, evidence of which—his diploma—must be submitted to the Board.

Further information regarding the examinations and their nature may be obtained by addressing the Surgeon General, U. S. Army, Washington, D. C.

NEWS.

—Dr. L. D. Tousely, 68 years old, died in Philadelphia, August 6, 1888.

—Professor Fritsch, of Breslau, has declined the invitation to go to the University of Würzburg.

—The foundation-stone of the new French Hospital in London was laid by the French Embassador July 21.

—Typhoid fever of a malignant type is said to be prevalent in the neighborhood of Wachapreague, Accomac County, Va.

—There were five deaths in Philadelphia from small-pox for the week ending August 4, and thirty-five from typhoid fever in the same period.

—Dr. Davis, of Whitwell's private asylum, says the *Canadian Practitioner*, August, 1888, reports the case of a woman sane only during pregnancy.

—An outbreak of typhoid fever has occurred in the Carmelite Convent at Hochelamea, near Montreal. All postulants who have not yet taken the habit were sent home.

—Dr. Bramann, of Berlin, whose name has become familiar to American readers through his connection with the late Emperor of Germany, has been recognized as *privat docent* in surgery.

—Dr. P. J. Higgins, of Wilkesbarre, Pa., declined to testify in an inquest before the coroner, unless his fee as medical expert was paid in advance. He was compelled by the coroner to give bonds in $500 to answer at court.

—Mr. Ridley, surgeon to Tullamore Gaol, committed suicide recently by cutting his throat with a razor. Since the death of Mr. Mandeville, the Member of Parliament who was confined in the gaol, Mr. Ridley is said to have been in a state of mental depression.

—Dr. Ludwid Julius Budge, Professor of Anatomy and Physiology in the University of Greifswald, has just died at the age of 77. His special studies have been on the nervous system. He demonstrated the origin of the sympathetic from the spinal cord. He also demonstrated the origin of the bile capillaries in the liver.

—At the semi-annual meeting of the Provincial Medical Board of the Province of Quebec, at Montreal, May 9, 1888 (*Canada Medical Record*, June, 1888), the examiners reported that forty-six candidates had passed. Thirty-two were rejected

upon certain subjects, and nine were totally rejected on all subjects.

Reports from Manatee, Florida, state that there have been two cases of yellow fever in forty-eight hours (ending August 6), but no deaths. Twenty possible cases have been sent to Pine Woods. Dr. Guitéras has declared that the suspicious case at Sandford, Florida, is not yellow fever. There are no new cases of yellow fever at Tampa, but there is one at Plant City.

—Dr. Henry Leffmann has been elected Lecturer on Chemistry at the Woman's Medical College of Pennsylvania, Philadelphia. The object of the Corporators in not electing Dr. Leffmann professor is said to be their desire to leave the chair vacant until it can be ascertained whether or not a qualified woman, who is also a graduate in medicine, can be obtained for the position.

—An employé in a planing-mill at Wellsville, Ohio, recently met with a peculiarly painful death while at work. He was standing in front of a "planer," when one of the "bits," a sharp piece of steel, three inches wide and four inches long, suddenly flew out of its place, striking him with great force in the abdomen and inflicting a terrible wound. The unfortunate man died almost instantly.

HUMOR.

An Anthropological Curiosity.—A double scull race.

When a thin man visits you, lodge him in the spare room, of course.—*Life.*

"I don't see why they call it vase*line*," said Bjones. "It's more like fat."—*Harper's Bazar.*

"How is that butter I sent you?" asked a Warwick grocer of a transient customer. "Better, thanks—gains strength every day."

It is reported that the dentists are taking the stump for revenue only all over the country. Politicians will have no patients with this sort of thing.—*Phila. Ledger.*

Mentor—Our idea of a strong-minded person would be one who can read the advertisement of a patented specific medicine, and yet not have the disease.—*Lowell Citizen.*

A woman in Salisbury, Eng., has been sent to prison for two years just for managing a farm. It was a baby farm, and there is no protection for infant industries under the British system.—*Ledger.*

Teacher: "Children, there is something within you that tells you when you have done wrong. What is it?" Small boy (gorged with green apples): "I know, sir. It's the colic."—*Detroit Free Press.*

"Why," said the young wife of a physician, who was given to boasting of her husband's professional skill, "he cured a patient of convalescence in less than twenty-four hours!"—*The Telegram.*

When they talked about "the nine" in Athens, it was the nine Muses. To-day, all over this country, "the nine" refers to baseball, excepting through the Middle and Western States, where it is understood to mean quinine.—*San Francisco Examiner.*

Wife—"John, dear, what would you do if I were to die?" Husband—"Don't speak of such a thing. I would be desperate." Wife—"Do you think you would marry again?" Husband—"Well, n–no; I don't think I would be as desperate as all that."—*Epoch.*

Names for Triplets.—*Truth* (N. Y.) says this is the latest credited to W. S. Gilbert: A friend was bewailing in his company that his wife had just presented him with triplets, all girls. "What am I to do with them?" asked the poor man. "I don't even know what to name them." "Oh," said Mr. Gilbert, "call the first Kate, the second Duplicate, and the third Triplicate."

OBITUARY.

JACOB H. WEHNER, M.D.

Dr. Jacob H. Wehner, of Germantown, died July 31, after an illness of three weeks. He was born in Philadelphia, February 11, 1840, and was educated at Dickinson College, Carlisle. After his graduation, he entered the Pennsylvania Medical College and received the degree of M.D. in 1861. He also attended lectures at the Jefferson College and the Medical Department of the University of Pennsylvania, and was for a time one of the Demonstrators at the latter institution.

During the late war, he was appointed Assistant Surgeon in the regular army, and for fourteen months was stationed at New Orleans. He was twice wounded on the battlefield while in the performance of his professional duties.

Dr. Wehner was a great friend to young physicians and assisted many of them into successful practice.

He leaves a wife and five children.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

College of Physicians and Surgeons

OF BALTIMORE, MD.

The Preliminary Course begins September 15th, 1888.

The Regular Session will open October 1st, 1888, and close about March 15th, 1889.

Attendance upon two full sessions is required for graduation.

The Clinical facilities of this school will be further increased by the new "City Hospital," which has a capacity of 300 beds.

For Catalogue, containing full information as to fees, etc., write to

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Clinical Lecture.

DISEASES OF THE THROAT AND NOSE.[1]

BY CARL SEILER, M.D.,

INSTRUCTOR IN LARYNGOLOGY IN THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

(Reported by Baldwin Gleason, M.D.)

Acute Tonsillitis.

Gentlemen: The first case this morning is one of acute tonsillitis The patient, a girl sixteen years of age, complains that her throat has been sore for some days; that this morning her jaws feel stiff and that she can scarcely open her mouth. Upon examining the fauces, we find the tonsils red and swollen, the inflammation involving the neighboring mucous membrane. You will also notice that the tongue is coated and the breath fetid. The patient is suffering severely. She has fever, pain, and a dry sensation in her throat, which she endeavors to relieve by frequent efforts at deglutition, which is, however, very painful. Her hearing seems somewhat impaired, and the cervical glands are enlarged, hardened, and painful to the touch. Upon the tonsils are several patches of soft cheesy material poured out from the crypts of the gland. These patches somewhat resemble those of diphtheria, and hence in Germany the disease is often called homœopathic diphtheria.

In this case we shall prescribe the usual treatment, which you have already seen to bring about a cure in a few days. When a patient presents himself at the dispensary, complaining that the throat has been sore for some days, and symptoms of acute tonsillitis are present, the fauces are first thoroughly washed with my antiseptic solution Then not only the inflamed tonsils, but the adjacent inflamed surfaces, are carefully painted with a solution of nitrate of silver, one drachm to the ounce, and the following gargle prescribed:

℞ Potasii bromidi . . . . . ℥iv
Potasii chloratis . . . . . ℥i
Tr. ferri chlor. . . . . f℥iiss
Ext. glycyrrhizæ . . . . . ℥i
Aquæ . . . . . q. s. ad f℥iv

M. Sig. A teaspoonful in water every two hours; gargle and swallow.

In this formula there is a chemical reaction between the tincture of the chloride of iron and the chlorate of potash, by which free chlorine is liberated, and so acts as a disinfectant. The resulting iron salt is highly astringent, while the bromide, besides its local action, diminishes the reflexes and adds to the patient's comfort.

After all, however, it is the argentic nitrate that relieves the suffering. It is worse than useless to apply a weak solution, as it is painful and seems to act as an irritant; while the application of a solution of one drachm to the ounce produces no disagreeable sensation, but is followed by a sense of comfort. After the application, a tenacious film of albuminate of silver forms, adhering closely to the surface (doubtless containing some undecomposed silver nitrate), and thus the astringent and sedative effects of the silver are kept up for some hours. If, after that time, the tonsils be examined, they will appear paler and smaller than when first seen.

[1] Delivered to the Fourth Year Class, University of Pennsylvania.

These applications are made in the dispensary once a day to patients requiring them, care being taken that none of the nitrate of silver solution drops from the cotton swab so as to get into the larynx, where it would produce severe spasm of the glottis. Sometimes a single application will effect a cure in acute tonsillitis. In no case has it been found necessary to make over three applications, the cure being usually complete on the fourth day.

At the end of ten days, the tonsils, if chronic hypertrophy exists, may be removed with the tonsillotome or wire snare, or shrunken away by repeated use of the galvano-cautery, and a return of the disease in this way prevented. Unless this is done, the patient who has had one attack of acute tonsillitis will certainly have others.

Influence of Nasal Catarrh on the Production of Acne.

The next case I bring before you simply to illustrate what I remarked in a former lecture on the effects of nasal catarrh in producing acne and other skin-diseases of the face. When you first saw this young woman, she was suffering from hypertrophic nasal catarrh, and her face was covered with comedones and pimples. As the result of treating her nasal disease, and without any other treatment, these have disappeared. She, however, complains that a small lump or tumor beneath the scapula, owing to its position, annoys her exceedingly. Now, we not only have acne upon the face, but it attacks the chest and back as well. This, then, may be a sebaceous cyst, and we will make a little opening through the skin and remove its contents, thus for the time being relieving our patient of this annoyance, although the cyst will probably fill up again unless its sac is dissected out. Instead of the usual cheesy contents of a sebaceous cyst, however, we find this to be a hard substance. It is nearly round, of about the size of a BB shot, and evidently calcareous. Upon section, as you see, there is a hard white nucleus, with softer and darker layers about it. It looks exactly like a calculus from the urinary bladder. It may be a sebaceous cyst that has undergone calcareous degeneration, but I confess I have never seen anything like it before. As a little wound is sometimes followed by erysipelas, and gives as much trouble as a big one, we shall use here an antiseptic dressing.

Nasal Polypus.

The third patient, Isaac B., 71 years old, came to the nose and throat dispensary May 17, complaining that he could not breathe through the left nostril. On inquiry, we learned that he had had asthma for 15 years, that there was pain low down in his throat on the left side, and cough and expectoration of pellets of mucus resembling boiled starch. An examination revealed a large polypus in the left nostril, while the right nostril was large and patulous. The mucous membrane in the lower or respiratory portion was somewhat atrophied, but that of the middle turbinated bone was swollen and pressed against the septum. There was also evidence of chronic laryngitis, the arytenoids being red and somewhat swollen, and the vocal chords muddy-looking.

After two days' preparatory treatment, Dr. Gleason removed the polypus, which was hard and somewhat fibrous in character. The operation was painless and bloodless, and gave immediate relief. It was followed, however, by an increase of the asthma, which prevented his sleeping. Dr. Gleason subsequently removed as much as possible of the hypertrophied mucous membrane of the middle turbinated bone with Farnham's alligator cutting-forceps, and I applied the electro-cautery to the same region on June 2.

On June 15, the patient reported that he had had no asthma since the last operation. A few days later, he reported that he had had a slight attack of asthma the day before, and Dr. Gleason applied the electro-cautery to the middle turbinated bone of the right nostril, destroying its hypertrophied mucous membrane. This was done on June 23. Since then, the patient has reported that he has had no asthma since the last operation, and that his pain and cough have left him.

We have here, then, a case of nasal asthma and cough due to pressure upon the septum in the region of the middle turbinated bones, and the man has been apparently cured by the treatment adopted. The mucous membrane of the nose presents a fairly healthy appearance. There are no symptoms of laryngitis, and the chords have regained their normal white color. That the cure will be permanent is probable, judging from the records of similar cases. We will direct the man, however, to continue using the modified Dobell's solution as a wash, which he has been doing since commencing treatment, and to report at the dispensary from time to time.

You will observe that it was not the presence of the polypus that produced the asthma and cough. Its removal was followed by increase of both these symptoms, probably as the result of increased swelling

of the mucous membrane of the middle turbinated bone in consequence of the operation, and the consequent increased pressure on the septum. Bear in mind, it is pressure on the septum in the region of the middle turbinated bone which produces these reflex symptoms. Patients with nasal asthma ordinarily tell you that the asthma began long before there was any polypus in the nose. This is undoubtedly the case in the majority of instances, and the asthma is frequently somewhat relieved after the appearance of the polypus. In the first place, there has occurred a polypoid degeneration of the mucous membrane of the middle turbinated bone, probably as the result of a local ethmoiditis, as claimed by Woakes, of London.

The swelling of the mucous membrane of the middle turbinated bone causes pressure upon the septum, and various reflex symptoms may result from this, especially if the same conditions exist in both nostrils and the septum is compressed, as it were, between the diseased middle turbinated bodies. As the polypus grows in the confined space between the turbinated body and the septum, the pressure upon the septum also increases, and the attacks of asthma are more frequent; finally, the polypus grows so large that it escapes into the lower or respiratory sinuses of the nose, and its weight stretches and decreases the diameter of its pedicle, thus relieving pressure upon the septum. Frequently, although the breathing through the affected nostril is impeded, the asthma and cough are not as bad at the time when the polypus is discovered.

The mere removal of polypi will not cure nasal asthma. The mucous membrane of the middle turbinated bones, frequently the whole mucous membrane of the nasal cavities and pharynx, must be made to assume a healthy condition. When this patient first presented himself, the slightest touch of a probe in certain parts of either nostril and the pharynx would bring on an attack of asthma, or, at least, violent coughing. This hyperæsthesia of the mucous membrane has disappeared since the removal of the pressure on the septum and the application of the iodine and iodide of potash solution in glycerine. This has been applied twice a week in the dispensary. The formula is as follows:

℞ Iodi . . . . . gr. viii
Potassii iodidi . . . . . gr. xxiv
Glycerini . . . . . f℥j
M.

He at one time also used the iron and potash gargle as a palliative while suffering from laryngitis.

1346 Spruce Street.

COMMUNICATIONS.

PROGRESS IN THE TREATMENT AND CARE OF THE INSANE: HOSPITALS RATHER THAN ASYLUMS.

BY D. H. MOUNT, A.M., M.D.,
BAY HEAD, N. J.

In these days of the telegraph, the telephone, the type-writer, and other instruments which we call the improvements of the nineteenth century, but which undoubtedly make us live all the faster and serve to tax the brain, it seems meet that attention and careful study should be given in proportion to the wrecks of humanity which all these economizers of time help to cause.

The statistics of the Life Insurance Company of the New York Produce Exchange are of interest in connection with this statement, for, as this is one of the oldest mercantile bodies in the country, and as it is in such places that steam, electricity, and all other devices which now enable a man to do the work in as many minutes as formerly it took so many days to accomplish are most appreciated, it probably furnishes as good an index for the purpose as can be found.

Nature seems always to provide a remedy, crude to be sure, when any injury occurs to the human mechanism; with man it remains to develop and carry out the hints so furnished.

To this are we indebted for the improvements in the treatment and care of those who have been rendered *hors de combat* by the strain produced from the methods of the current century.

Those people who deplore the passing away of the old stage-coach days, the slow post, and who think that the days of our grandfathers were more comfortable to live in than the present, are certainly right, if it cannot be shown that, as the evil has progressed, the remedy has kept pace with it. If insanity has increased, and it can be shown that the new cases received each year are out of proportion to the growth of the population, and that the recoveries are fewer, then these wishers after the "good old times" are correct.

Statistics in regard to the number and

condition of the insane will be of interest to those desiring this information.

These will show at a first glance that insanity has increased out of proportion to the increase of the population, notably in New York; but several important points must be borne in mind whilst considering them. First, the different view with which almost all people now look on the disease called insanity. Formerly it was considered a disgrace for one of a family to be known as being insane; hence such cases were kept secluded as much as possible. Instances are numerous in which families, even in very ordinary circumstances, have had small brick or stone houses built to confine an insane relative in, rather than have it noised about the county of which they were residents that they had a relative who was crazy and in the lunatic asylum. All of these cases were, of course, lost to statistics, whilst now it is a comparatively rare thing to find a concealed case, and everything gets into the enumeration. Again, from better care and improved methods of treating them, the chronic insane live longer than formerly, thus increasing the grand total each year.

Of the foreign population increasing our rate, much has been written and spoken of. That these people do increase the rate seems to be an established fact, nor can it be wondered at when it is looked into closely. Here are a number of people who have been living quietly at home with probably no ambition for the future beyond the condition of life which their fathers enjoyed. (I speak more particularly of the German rustic, for he it is who predominates among our foreign insane.) One of these hears wonderful stories about the New World; he sees a former resident of his village return for a visit who left there for America but a short time before, poor, but who now has plenty of money; he determines to emigrate; he takes the savings of his lifetime, makes the voyage, and arrives here; but what a disappointment often awaits him.

He finds, instead of the quiet village people he left at home, a multitude of people, all striving to their utmost for the almighty dollar; work he finds hard to get; his money all gone, no friends to encourage him, what wonder, then, that despair, suicide, or insanity follows? Thus, whilst had he remained at home he would most probably have enjoyed good mental health, here from worry and disappointment he becomes insane.

Much has been done in this country by alienists such as Mills, Seguin, Spitzka, Hughes, and others, so that in looking carefully over the field it will be found that, as a new phase of the disease presents itself, skill in treating it has been developed.

This is more particularly true of acute cases and of those cases which formerly were not recognized as pertaining to insanity, but which are now known as such, and by treatment a threatened attack of the disease prevented.

Blandford, in a recent address, made use of the following expressions in regard to the treatment of the insomnia in acute mania:

"When I began to practice, there was nothing but opium and its compounds; but to give opium or morphine to a patient in this stage would certainly have the effect of not producing but of preventing sleep; now there are the bromides, urethan, and numerous other hypnotics."

What Blandford calls the moral treatment has also been put in practice most successfully. Patients are now more carefully classified, and an attempt is made, with good results, to awaken a dormant sense by throwing them in contact with rational people, the Belgian plan of placing patients in the families of farmers being particularly successful.

The old custom of putting every obstreperous patient under restraint by means of apparatus has been done away with, I may say, in all the private asylums, and, where the patient's friends are able to pay for the extra attention involved, in most of the large institutions also; some of the more advanced ones maintain that they have no restraining apparatus about the place.

Whilst the writer was junior interne in a large New York hospital, there were numerous surgical dressings to do, and he found that in order to get through the work between 9 A.M. and 1 P.M. his time must be economized. Soon it was seen that, among the more painful dressings, time could be gained by carefully observing the patient. It was found that when the patient expressed his feelings by making great outcries whilst the dressing was being done, that on the completion of the dressing he was in good condition; per contra, it was found that those patients who said not a word, but who bore pain with firm-set jaws and white contracted lips, needed more attention afterward and really suffered more and were worse off than those who had made so much noise. It was felt that it was with the one who was making the noise as if the surplus steam was going off through a safety-valve; while with the other, as if the safety-valve had been

tied down, and an explosion imminent at any moment. With the insane who are being restrained, the same thing is undoubtedly true; their sufferings from their delusions causing them quite as much pain as if everything were true which they imagine.

A patient in my care, whose father is the owner of a palatial residence just outside of New York, one night went to her window and declared she saw her father's house burning. She described the different phases of the fire, and called on imaginary people present to save her father and mother from the flames.

Of course, soothing measures could avail nothing in such a case as this, but grs. lx of sodium brom. were given by force, after which the patient was allowed to move about the room as before. In an hour, an additional 60 grs. were given in the same manner, which was followed soon after by a complete quiet, and finally sleep. Formerly, in a case like this, the straight-jacket would have been used; but would not such treatment have put the patient in the same position as the one with the firm-set jaws mentioned above—or, in other words, would not the safety-valve have been tied down? On another occasion, when this same patient was in a "walking mood," and when it seemed proper to take some active measures to get her in a recumbent position because of the swelling of the feet and legs, and when she was observed leaning against the wall asleep, it seemed an opportune moment quietly to move her to her bed, and, by using mild force, get her to remain there. This was accordingly done, but with the opposite effect from that desired, for almost at once she became aroused, and, the longer she was held, the more violent she became, until it was seen that no good could be accomplished. Here, again, the bromide of sodium was given in large doses and with the same good effect as before.

In the old days, when, as Blandford says, they had nothing but opium and its compounds, and when a patient was in such a condition, restraining apparatus would surely have been used because there would have been nothing else to have resorted to—would not she, almost to a certainty, have had an attack of acute mania? As it was, the bromide put her in a profound sleep, which lasted for some hours, on waking from which she ate the food which had been placed at her bedside, and then again went to sleep to awake at intervals and take her food as before.

In such cases, the disposition among the more advanced teachers is to give the patient the greatest amount of freedom consistent with safety.

In quite similar cases apparently, but where the patient's brain was anæmic, the writer has procured quite as good an effect from the administration of small doses of either alcohol or opium. When the ophthalmoscope can be used, the differential diagnosis between congestion and anæmia is, of course, easy; but where the patient persists in keeping her eyes closed, or will not keep quiet, this means of deciding is out of the question, and the other physical signs must be the guide. These, however, cannot always be relied on to a certainty, for the anæmic patient will often have a fair pulse, and, more often than not, a flushed face. This treatment of congestion and anæmia is well illustrated in the headache of the sane. Their anæmic headache is cured by ammonia, a good dinner, or some other kind of stimulant, whilst the bromides take care of the congestive form. As progress has abolished for the most part some kinds of restraining apparatus, it has also brought other kinds into use. One in particular, which prevents the habit of self-abuse in the female, is worthy of mention.

None but those who have had such patients under their care, and who have tried hard to have them stop their habit, can have any idea what a relief an apparatus of this kind is, for, however much the patient may wish to prevent it, she oftentimes yields to temptation if left alone at night, and in a short time may undo the good results obtained after weeks of care. The apparatus is not a disagreeable one, and is worn readily at night by those particularly who are afflicted with sub-acute melancholia and who wish honestly to break themselves of the habit. This is a great advance, because to remove, or in a measure control, masturbation in the female is to remove a potent cause for insanity.

The giving of food forcibly to those who, with suicidal intent, refuse nourishment has been done away with by many, it having been found by close observers that if food is kept constantly before this class of patients, and if it is replaced by fresh food at regular intervals, whether the first has been touched by the patient or not, they will, if not too closely watched, steal a small quantity of it and eat it; then, if no notice is taken of it, in a few hours they will take more, until finally they will in a short time be found eating their full ration. What Blandford calls "judicious neglect" is, I think, very

applicable in such cases. I quote a typical case from my history-book:

Monday, Aug. 20.—Patient took breakfast as usual this morning, but at dinner refuses everything and declares that "her insides are all gone" and that she could not take anything even "if she *dared* to."

Tuesday, 21.—Absolutely refuses to dress herself or be dressed; pulls clothing off as fast as put on; breakfast with cup of milk left in room. 1 P.M.—Has taken no food; breakfast removed, and dinner with fresh cup of milk put in its place. 4 P.M.—Whilst unnoticed has drank cup of milk, which was replaced at once by more. 6 P.M.—Dinner removed and replaced by supper.

Wednesday, 22, 6 A.M.—Milk has disappeared; more milk placed in same manner, which also disappeared as soon as patient could take it without being observed, which was in a few minutes; more milk supplied and breakfast taken in room at regular time, the supper of previous night being then removed. 9 P.M.—During the rest of the day, the same process was gone through with as before, the patient taking three cups of milk when unobserved, but leaving the other food untouched.

Thursday, 9.30 A.M.—Whilst thinking herself unobserved, patient has eaten everything which was taken in for breakfast, not leaving a scrap of anything. Dinner was eaten in the same way, and long before supper-time she asked how soon it would be ready.

In pursuing this plan, great care is taken to have the food changed at the proper intervals, and that it should be made as tempting as possible, not only to the sight, but also to the sense of smell. I have heard patients say, when a savory dish was being carried in by an attendant: "It smells good, but I must not eat it."

Former habits and tastes bear looking into, in this respect. I have had a patient who took nothing but ice-cream for several days. It was supplied to her, all she would take, and it was good, too, according to her estimate for its taste; but the doctor watched it, because it contained albumen, starch, sugar, etc., and he was well satisfied. Of the different medicines used, hyoscyamus and its alkaloids stand in the front rank, whilst others are being constantly tried and put among the feasible remedies. One thing seems worthy of note, and that is that heroic doses, given at long intervals in the disturbed cases, are of more avail than small doses given frequently. Hypodermic medication may be made useful in the future, and cranial surgery is pushing to the front and received with great favor. Whatever progress has been made in the treatment and care of the insane in the public lunatic asylums is, I firmly believe, comparatively little compared with what will be done in the near future, if all signs are true.

Dr. Hughes, of St. Louis, in a short but able article in the *Alienist and Neurologist*, January, 1888, calls for the separation of all political influence from the State lunatic institutions, and gives the best of reasons therefor.

Suppose we go still further and ask for lunatic hospitals conducted on the same plan as any other hospital, where a regular house staff could be admitted by competitive examination, and the hospitals located near enough to the cities so that specialists could be of the visiting staff and constitute the examining board. This would do away with political influence for the most part. Take, for instance, Bellevue Hospital, New York, for if there is any place in the world where political influence reigns supreme it is in the city of New York; yet be it said to the credit of the hospital that the man who comes up for examination, among the large number who usually come before the examining board for the few positions, knows that his knowledge of medicine will get him the coveted position, not his fine appearance, his money, or political influence. Could every city or town in each State which is large enough to have a hospital have a department for the insane attached to it, where the conditions as regards the visiting and house staff could be as before mentioned, I believe that much progress could be made, because the hospitals would be smaller than the asylums; the patients would therefore be more directly under the care of the house staff, for there would be fewer to look after, and much that is now left to the observation of attendants for information could be obtained by the house staff itself. The specialist would be benefited, because he would have opportunities of observing patients during the whole course of their illness, many of whom are now as a closed book to him, once he has sent them to an asylum, and for the same reason the patient would be benefited, because the specialist would have a wider field of observation.

In following out this plan, the asylums could be used as hospitals for the incurables. In general surgery and medicine, we have our hospitals for incurables, and why not have the same for the insane? As it is now,

the acute cases of insanity and the incurables are all sent to the same institution. What would be thought of the medical man to-day who would send a case of pneumonia to the home for consumptives, or a fracture to the hospital for incurables? And yet is not that what we are all doing with our acute insane in this the nineteenth century?

That the asylums are overcrowded, and more work is given the medical men to do than they can observe closely, instance the experience of the New York *World* reporter who stayed a number of days in an asylum and wrote a lengthy article thereon, which brought unfavorable comment on the management of the institution from the public. Could such a thing have happened, had the conditions been such as have been suggested? Could this reporter have accomplished the feat so easily, had there been three medical men looking after, say, one hundred patients in their division, and a "visiting" staff going the rounds once a day? Of the practices of hospital beats, every "hospital man" is familiar; and whilst I have seen them admitted to the wards either through hasty judgment or curiosity to see "how they did it," my experience is that, however well simulated their trouble—and it is often as well put on as the reporter's—they seldom remain longer than one day. During my service, a patient was brought to the hospital by an agent of one of the merchant princes of New York, who, through a salaried man doing nothing other than looking after the sick poor, took this means of distributing his charity in an unostentatious manner.

The patient was supposed to be suffering from hemiplegia, and all the signs pointed to that as a correct diagnosis; but something about the appearance of the patient led to a thorough test being made; something led to the belief that she was a sham.

Etherization was accordingly ordered, as the most sure means of making the diagnosis. The patient, on hearing this, protested most vehemently, and, as her protests were not listened to, had the agent take her from the hospital. The agent, an old man, in a few weeks returned and apologized for the trouble he had made (for he was most emphatic at the time in his recommendation of the patient—"she was his old Sunday-school scholar," etc.), and said he had been completely deceived, for, on calling to see her a few nights before, he had found her drunk, and that for some fancied slight she had caught hold of him and forcibly ejected him from the house. All "hospital men" will recall instances of similar kinds. Of the asylum men, their opportunities of observation must necessarily be not so great, because two medical men looking after, oftentimes, from 700 to 800 patients (for the superintendent can in such a large institution have little or no time for medical work) must find it impossible to make the finer distinctions; and, as before mentioned, the attendants must be relied on chiefly for information. The writer is aware that there are at least three institutions in the country conducted somewhat on the plan suggested. That is to say, they are branches of general hospitals; but, unfortunately, the customs of a hospital, in regard to the visiting staff and the house staff, are not carried out.

Space forbids here any full discussion of such a fruitful subject; but it is hoped by the writer that the hint furnished may lead to some good, and that if his suggestion of small hospitals for the insane, instead of large asylums, should meet with the approval of others, the proposition may be put in practice and brought to success.

DIAGNOSIS OF SCARLET FEVER.

HORACE G. WETHERILL,
TRENTON, N. J.

There are changes and modifications being wrought in diseases from year to year, and pathological conditions are modified by the circumstances attending and present in each case of disease; this doctrine now believed to be as true as that the evolution of an animal with new anatomical features may be a creation of new environment. It is hardly necessary, in support of this, to more than call attention to the numerous diseases of ancient times, to which the present generation are not subject; and one need only refer to the few new diseases of the past century, to which the previous medical history of the world furnishes no analogue. When one looks back in review over the various modes of living of the human animal, and considers how great the change has been from the habits of life of man in the high civilization of this age, as compared with those in which he was created, or those even in which numbers of the race still live to-day, it seems no more remarkable that his diseases should be modified by these circumstances than that there should be greater differences (physically) between men than between some of the human race and the monkey.

The individuality of each case impresses itself more and more each day on the prac-

ticing physician, and he is often puzzled to know just what answer to give when accosted by an anxious friend of his patient with the inquiry "What is it, Doctor?" For the case is not typical (so very few are); there are features like those of typhoid fever, and yet the whole aspect of the case will not warrant the proper use of that name, or in fact of any but that execrable expression "A complication of diseases," behind which barrier one retires to wait, like Mr. Micawber, for something to turn up.

Even those diseases which under ordinary circumstances seem so easy of recognition may be masked by unusual features, so that there may be no knowledge attainable of some of the circumstances of the case, such as exposure to contagion; and we lose valuable time in treating the first cases in an epidemic by waiting for the typical signs.

The above is only a preface to the history of some cases of scarlet fever presenting anomalous symptoms, and is offered simply as a suggestion that this disease may be undergoing a modification in its characteristics at the present time, just as typhoid fever is by some believed to be doing in certain malarious portions of this country.

Dr. Woodward, in his paper before the Medical Congress at Philadelphia in 1876, suggested the name typho-malarial, which has been found to be applicable to many cases, and has been very generally adopted throughout this country in order to mark a disease which is different in some respects from the characteristic typhoid fever. "According to Mayer, the merit of having shown measles to be a malady distinct from scarlatina must be ascribed to Forester and Sydenham. It is not clear, however, that the two diseases were accurately differentiated till the close of the last century, and notably by Withering in 1792." [1]

These two diseases, it is said in most text-books upon the subject, are now so clearly defined and differentiated that no mistake should be made in recognizing them; but that cases may occur early in an epidemic, or when no exposure to either disease is known to have occurred—cases which defy absolute recognition—has been maintained as a fact by deeper thinkers and closer observers than your essayist; and this position can but be supported by two of the cases cited below.

The first of these cases for which medical attendance was asked was that of a child five years old. He had been complaining for a few days, and had an eruption which was supposed to be measles, and which so resembled the eruption of measles that it was pronounced to be this disease by a physician. The case presented the coryza, congested eyes, and catarrhal bronchitis common in the early stage of measles, and the eruption presented none of the efflorescence or diffused scarlet-blush of scarlatina, but, on the contrary, was distinctly maculated and was of a dull or deep-red color, disappearing on pressure; the tongue was not the strawberry tongue of scarlatina, and, while there was sore throat, it was no worse than is often found in measles, and moreover had no appearance on the uvula or elsewhere to lead to any opinion but that the case was one of measles and of no more than ordinary severity. The child was one of a family of four children living in the country, and had not been off the farm or had young company for many weeks, and had not been exposed to any contagious disease of any kind. The other members of the family were supposed to have been free from any exposure also, though a boy and girl of the family came into the city of Trenton to school every day.

This was the state of affairs as presented to the attending physician on Monday, February 13, 1888.

The case progressed favorably, without any untoward symptoms or any indications of being more than an ordinary case of measles, until Thursday evening. The breathing then quickly became difficult, there was tumefaction about the neck, and the symptoms became alarming. Friday morning found the conditions materially worse, the throat being covered with a diphtheritic membrane and the case presenting all the throat-symptoms of a malignant scarlatina anginosa, with fetid breath and an excoriating discharge from the nose. The tongue was brown and covered with sordes. The child struggled for breath through the day, and died near midnight.

On this day (Friday), an older son was taken ill with sore throat and an eruption, having had a slight chill the day before. He had a strawberry tongue, and the soft palate was characteristic in appearance, and so was the eruption a day later. He had a typical scarlatina, which ran the usual course to recovery.

A day or two later, an older daughter also began with the disease, but the signs (eruption, etc.) were not so marked. It was a regular case, and advanced slowly to recovery.

[1] Pepper's System of Medicine, vol. i, page 557.

Now, to go back and trace the means by which the disease was brought to this house leads us to the consideration of a second case, presenting the disease in an unusual form.

The remaining child in this family was a girl 13 or 14 years old, going in the city to school every day before this outbreak. A close examination of this child led to the discovery that there was a slight desquamation going on about her wrists; her face was puffy, and an examination of her urine showed albumin, epithelium, and a few epithelial casts.

Questioning developed the fact that for a day or two in the preceding week she did not feel well, had a slight sore throat, and stayed away from school, and at the house of a relative in the city. She did not see any eruption or know that she had any, nor did the sore throat last more than a day or two. She took no medicine, and went home on Friday (February 10), three days before the little boy was taken sick. Albumin was present in the urine of this patient for a week or two, disappearing at times for a day or two, and again appearing; there was œdema of the face, headache, loss of appetite, etc., but all soon disappeared and she was soon well.

She unquestionably was the medium by which the other cases were established, and it was shown that she had not been exposed to the disease, so far as she knew, excepting in passing at school a girl who had had it three weeks before, but who had on the same dress on returning to school that she had on when going home sick; there had been no contact, but simply a passing of each other in going about the school-room. It would be interesting to know with how much care this clothing had been disinfected or aired, but it can hardly be doubted that the period was too short in which this young girl was allowed to return to school, after being ill with scarlet fever, to be shut up for a whole day with a number of susceptible young people.

The fifth case was in the house of the relative in Trenton, at which the patient last spoken of staid for a few days while indisposed, and was so unlike typical scarlatina as to lead to great doubt in the mind of the attending physician that it was truly this disease, though he had seen the patient frequently, and was on the watch for it because of the known exposure. The child remained well for fourteen days after exposure, and was considered past any chance of being ill, as the ordinary period of incubation is so short—three to seven days—and may even be very much shorter, as the next case will show. On about the fourteenth day she had slight rigors, and on the next day a slight rise of temperature, with a faint blush in the throat, which was very little sore. She also had an indistinct and ill-defined rash on the skin, under the clothing only. These signs soon disappeared, and, without other symptoms, the recovery was established. Taking into consideration all the facts, this was considered a case of scarlatina, and was, in my opinion, very properly quarantined for some time as such and reported to the Board of Health. But what a different view of this case might have been taken, and how grave the possible consequences, if the history of exposure had been less clearly known.

Case six is of a kind unique in the experience of those physicians to whom it has been cited, and in my own, though similar cases have been reported and may have occurred quite often without being known as having originated in so direct a way, *i. e.*, by inoculation. The patient was about 48 years of age. He had had cardiac asthma and a catarrhal bronchitis for a year or more, accompanied with tickling in the throat and annoying cough at night, with little if any expectoration. The uvula was found greatly elongated and relaxed so that it dragged down on the base of the tongue and against the posterior wall of the pharynx when the patient was in a recumbent position. On Tuesday, February 21, 1888, an effort was made to amputate the uvula. Forceps were fastened on it, but so much nausea was induced (he vomited his breakfast in my office), and the throat was so sensitive, that the effort had to be abandoned. The next morning, with the aid of a spray of a two per cent. solution of cocaine, the amputation was easily accomplished, and without pain or unpleasant symptoms, such as occurred the day before.

The next day he had pain in the back and legs and head, no appetite, nausea, and toward evening a severe chill. The throat presented a scarlet appearance and was quite sore. The next day, Friday, he vomited freely, had great pain in his throat, which was intensely inflamed and had a diphtheritic patch on the stump of the uvula. In the evening he had a temperature of 102° and was covered with an eruption characteristic of scarlatina; pulse 130. This patient had the disease severely in a typical way; it ran a regular course, and recovery followed in due time without accident or complication.

excepting that there was albumin in the urine one day, and an abundance of epithelium all through the stage of desquamation from the skin; this, however, cannot be an unusual occurrence, as no doubt the epithelium of the mucous membranes that have been covered with the eruption is thrown off just as the epithelium of the skin is. He had not been exposed to scarlet fever in any way excepting through me, the cases above related, with one exception, being in my charge at the time.

The atomizer, scissors, forceps, etc., had not been near the other patients, but a pocket tongue-depresser used in his mouth when the amputation was done had been used in the mouth of the boy that died, five days before, when the disease was still supposed to be measles, but not since. It had been washed frequently and used in other mouths meanwhile, and no trouble had resulted in any case, though it had been in the mouths of children, and it is my firm belief that there would have been none here if the operation had not been of a kind to open the mucous membrane. Evidently this case was one of inoculation; this opinion is supported by the short period of incubation (thirty-six hours) from the time of operation to the time of chill, and by the fact that the patient had long passed the age when there is ready susceptibility to the disease.

I had not been in the presence of scarlet fever patients for more than forty hours before the amputation was done, and it seems hardly likely that the disease was carried by my hands or person, more especially as my hands were not in the mouth, nor was anything else but the instruments named.

This series of cases presents some unusual features, and it is easy to make practical deductions from them which may be useful in the conduct of other cases, for it is only by a careful observation of the unusual features in a disease that we can hope to be prepared to meet and conquer emergencies as they arise. 1. Scarlatina often deviates from the true type, as we know it, and may be so masked as to resemble another disease so closely as to make the differential diagnosis very difficult, or even impossible in its early stages, and sometimes in any stage. 2. The danger of contagion from these cases is increased greatly, and the fever contracted in this way may be of a severe and fatal kind, so that 3, this is a disease we should exercise unusual care in detecting and quarantining. 4. The disease may be inoculated when the virus has access to the blood, and more than ordinary care in cleansing instruments such as the tongue-depresser and thermometer is required, and there should be thorough disinfection before their use in any surgical operation. The same disinfection is necessary also before obstetrical cases are attended. 5. Careful and frequent examination of the urine for albumin, epithelium, and casts is a valuable diagnostic measure, and may forewarn the attendant of approaching danger of uremia, and may save a sudden fatal termination of the case when it is supposed the patient is convalescent.

AN OPERATION FOR STRANGULATED INGUINO-SCROTAL HERNIA.

BY B. BRABSON CATES, M.D. (UNIV. PA.),
MARYVILLE, TENNESSEE.

Sam Curtis, man, white, æt. 40, laborer in a steam saw-mill, has been troubled with hernia since he was ten years old; has never worn a truss, and never had any difficulty in reducing the protrusion until June 12, 1888, when, after some heavy lifting, the hernia came down and defied all his efforts to replace it. He said nothing about his trouble, but kept at his work, suffering with pain over the tumor and in the region of the umbilicus, and with constipation and tenesmus, until early in the morning of June 14. He was then seized with nausea and vomiting, and the pain increased so that he was compelled to seek medical aid. My friend, Dr. J. W Hannum, was summoned, but, owing to the fact that the patient lived at a considerable distance in the country, did not get to see him till about 10 A.M.

Having failed to effect reduction after trying all available means, Dr. Hannum courteously summoned me to see the patient with him in consultation. I found the man in the afternoon of the same day, living in a small cabin, the hygienic surroundings of which were deplorable. His face was flushed, his features pinched, his eyes bright, his mouth dry, his tongue furred. He had considerable thirst. His bowels were constipated. He had slight fever. His pulse was small and rapid, and his respiration was accelerated. On examination, I found on the right side a smooth, oval, tense, semi-elastic tumor, tympanitic on percussion. The scrotum on the same side was greatly distended and so very tense that it could scarcely be indented by very firm pressure, while the tumor extended well out along Poupart's ligament. I diagnosticated an inguino-scrotal enterocele with some of the

characteristics of an inguino-crural hernia, inasmuch as while the scrotum was distended to its utmost, an additional loop of intestine descended and protruded outward along the folds of the groin, as was proved by a subsequent dissection. I employed judicious taxis, remembering the injunction laid down in Prof. Ashhurst's surgery that "if a moderate and cautious employment of the taxis does not afford relief, the sole hope of safety lies in the use of the knife." Taxis did not make the slightest impression on the tumor.

Dr. Hannum and I then agreed to etherize our patient, with the understanding that, should we fail to reduce the hernia, we were to operate, a determination which was accepted by our patient. Having fully etherized him, and employing taxis to no avail, Dr. Hannum asked me to operate, which I did, cutting directly down upon the tumor in its long axis, so that, as recommended by Prof. Ashhurst, the position of the external ring would be a little above the middle of my incision, which was about three inches in length. I picked up each layer of tissue and divided it upon a grooved director until I relieved the stricture in the neck of the sac. I performed the ordinary operation of opening the sac, having first tried Petit's method. I found the bowel considerably congested and swollen. Dr. Hannum then reduced the bowel and stitched up the wound, dressing it strictly antiseptically. Strict antisepsis was observed both before and after the operation.

The patient rallied well, but complained of slight pain in the region of the umbilicus. We left him late in the afternoon, with strict orders as to diet, and the use of opiates should the pain continue; but, happily, opiates were not needed.

I saw him the following day about 10 o'clock A.M., when his temperature stood at 100.1°; his pulse was 104, and his respiration 18, while the pain had disappeared from the region of the umbilicus. His tongue was coated yellow; his bowels had moved four times during the night. To check this, I ordered opiates. June 16, at 2 P.M., his temperature was 100.1°, his pulse 82, his respirations 15. His tongue was still furred and his bowels had moved twice. June 17, at 2 P.M., his temperature was 99.3°, his pulse 75, his respirations 15. I now drew off his urine, which was scanty and high-colored. His bowels had not troubled him. June 19, his temperature was 99.1°, his respirations 14, his pulse 72. His bowels had not moved and his kidneys were acting well. June 22, his temperature was 98.1°, his pulse 66, his respirations 15. June 26, his constitutional symptoms being normal, and the wound having thoroughly healed except at the lower end, which showed a place the size of a pea, which would have to heal by second intention, I fitted him with a truss and dismissed him as cured.

The treatment during the first four or five days subsequent to the operation consisted in enforcing absolute rest on the back in bed, not even rising to respond to the calls of nature; with the use of a simple milk diet at first, and afterward an allowance of chicken broth and a little of the white of the chicken. When I dismissed him, I allowed him to return to a mixed diet.

It seems clear to my mind that this case tends to confirm the general opinion of surgeons, that a cutting operation, with the advantages of modern antiseptic methods, should be undertaken whenever a hernia does not yield to comparatively gentle taxis, and that the prospects of a patient are much better where the sac is opened than when the hernia is restored without doing this.

TYPHOID FEVER A CONTAGIOUS DISEASE.

BY JAMES W. PRICE, M.D.,
FORT SMITH, ARKANSAS.

That form of fever known among medical authors as typhoid fever has in it certain symptoms which may be easily and readily defined; to go into a description of its diagnosis and prognosis would be foreign to the object in view in addressing you on this occasion

The point which presents itself more forcibly to my mind, the one upon which I shall base my argument, is: "Is Typhoid Fever Contagious?" Can it be transmitted from a typhoid patient to another person who may be brought in contact with the case, but who at the time is in health and free from any form of indisposition whatever? I am aware of the fact that the conflicting opinions among the medical fraternity upon this peculiar and interesting subject have been discussed elaborately for years; but if there has ever been a definite conclusion reached I have yet to learn of it, though I have had an experience of some thirty or forty years in the profession. Each man assumes that his views are right and that his conclusions are based upon strict medical science. After investigating authors upon the subject and summing up the evidence, I am forced, from an honest convic-

tion, to believe that typhoid fever is clearly a contagious and infectious disease, and may be imparted to others who are totally free from any fever-germs. Dr. Flint says: "With respect to the contagiousness of the disease, there has not been unanimity of opinion. That it may be communicated under certain circumstances is certain, and that it frequently or generally originates spontaneously, irrespective of contagion or infection, is perhaps equally certain."

While acting surgeon in the Confederate army in the year 1860, my regiment was stationed near Savannah, Ga., upon a high dry pine-barren, with no swamps or lagoons from which could have possibly arisen malaria or miasm sufficient to have produced typhoid fever (I suppose some of the latter-day saints would have termed it typho-malarial); and yet we had, in a few days, some nineteen or twenty cases of genuine typhoid fever. Having railroad facilities at my command, I decided to send my patients home to their friends among the mountains, where they soon recovered and returned to their command. But now for the sequel. The report came back to the surgeon from the friends of these patients: "For God's sake, never send any more typhoid-fever patients home, as the disease has spread throughout the neighborhood." The conclusion is inevitable, that the typho-malarial hobby was exploded by the result which occurred on this occasion.

Flint says: "The contagiousness of typhiod fever is proved by instances in which persons, having contracted the disease in one locality, go to another in which the disease was not prevailing, and, of the residents in the latter locality, with whom they are brought in contact, a greater or less number become affected."

The contagiousness of this disease, either from direct or indirect causes, may be inferred from a writer in the *Medical Press*, who says that, in the examination of a certain barracks where this disease had prevailed, it was "ascertained that three of the recent cases had used the clothing and bedding of men that had been attacked. This led to closer examination of the clothing, and it was then discovered that the linings of the trousers were, almost without exception, soiled by dried fecal matter, of which a part probably had its origin in typhoid fever."

I have endeavored, in a succinct way, to present my views, trusting I might add something which may lead to investigation and draw out some eminent Boanerges who will enlighten the world upon the subject.

Society Reports.

PHILADELPHIA CLINICAL SOCIETY.

Stated Meeting, April 27, 1888.

The President, Dr. Mary E. Allen, in the chair.

Dr. Clara Marshall read a paper entitled

A Report of Two Cases of Chorea Occurring During Pregnancy.

Case I.—Sallie M., 18 years old, single; menses established when 13 years old, always regular. Chorea was developed at the age of 10, increasing in severity (though to a more marked extent during pregnancy) until the time of her admission into the wards of the Philadelphia Hospital, in March, 1883. She attributes the chorea to mal-treatment at the hands of a relative, who was her caretaker. At the time of her admission into the hospital, the choreic movements were violent to the last degree, the patient not having the slightest control over herself, and the movements being sufficient to prevent her remaining in bed without restraint.

As the patient was pregnant, the advisability of terminating the gestation was considered; but finally she was transferred to the nervous wards, where, under the care of Dr. Charles K. Mills, she slowly but decidedly improved. The treatment, while in the nervous wards, consisted in the administration of antispasmodics and tonics: a combination of potassium bromide, with conium juice and liquor potass. arsenitis, was the principal medication. Careful attention was also paid to the diet, and stimulants, in the form of milk punch chiefly, were given.

The choreic movements were not present during sleep. The patient asserts that she was not conscious of being brought to the hospital, and that she did not recover consciousness until after she had been transferred to the medical wards. She was returned to the obstetrical ward June 7, 1883, at which time the choreic movements had almost ceased, and in this respect she remained in about the same condition until delivery. She was delivered of a child, weighing 5.8 lbs., June 24, after a normal delivery. June 30: Patient's general condition good; bowels regular; tongue clean; her hands lie perfectly still, except when attention is called to them, when they twitch slightly. She sleeps well; is taking no antispasmodics.

The lying-in period was normal; the convulsive movements disappearing entirely. She left the hospital in due time, taking her baby with her. Nov. 24, 1885, Sara M. was again admitted, with her second baby, æt. 5 days; no chorea. She was discharged Dec. 24, 1885, at which time mother and child were in good condition.

Case II occurred in the practice of Dr. Laure Hulme, of West Chester.—W. S., æt. 24; married; three children; youngest three months, oldest three and a half years. The chorea dates from the first pregnancy, lasting through each pregnancy, with slight improvement after delivery. The second delivery was a breech presentation, with still-born infant. No improvement followed this second delivery, as she almost at once became pregnant for the third time. There was at this time much nausea, which prevented the retention of medicines by the stomach. She could not stand alone, and walked with great difficulty; her arms and hands went through certain irregular movements before she could use them to carry out her wishes; the tendon reflexes were exaggerated; pupils responded normally to light; appetite good; bowels regular; no albuminuria.

She was delivered in July, 1887 (the labor being short and easy), after which she began at once taking ext. cimicifugæ fld. ʒ iij–ʒ iv a day, upon which she decidedly improved; she could walk very much better, but was not quite steady upon her feet, had to make several ineffectual attempts before being able to co-ordinate her movements. She continued to improve under the administration of cimicifuga. Her speech, which was much impaired when first seen, soon lost this feature, except occasionally; the facial movements began to be slight and ceased to be constant; uterus and appendages normal; heart's action regular; no sensitive point on spine; the insomnia disappeared, as well as the twitching during sleep. It might be stated here that, although there was no history of chorea previous to marriage, yet the patient had always been very nervous. Different remedies were tried in the case—hyoscyamus and Fowler's solution being the principal ones; all seemed useless until cimicifuga was given a trial, which proved beneficial.

As to the causes of chorea of gestation, Barnes says that it is doubtful whether chorea arises in the course of gestation, as a new disease. In case first it was a disease of childhood (partly aggravated by gestation). In case second it first manifested itself during pregnancy, though the patient was one with a nervous diathesis, which is insisted upon by Barnes as a foundation for chorea of gestation, where there has been no chorea of childhood. Since chorea involves danger to life of fœtus and mother, the question of terminating the pregnancy comes up (especially in the interest of the mother). Nature often solves this problem, and sometimes, even then, through procrastination, the mother's life may be lost. Barnes reports nine fatal cases; in five of these premature labor set in spontaneously, in four it was induced.

Besides medication and induction of premature labor, dilatation of the cervix uteri has been tried by Dr. W. F. Wade (Physician to General Hospital, Birmingham, England). In this case potass. bromide, tinct. valerian., chloral, cannabis Ind., were used without benefit; finally dilatation of the cervix was resorted to, under chloroform. Total amount of dilatation, 2½ inches. This was followed by steady improvement; there remaining only a slight twitching of the fingers of the right hand, and a little fidgetiness when watched, which disappeared after the birth of the child. Chorea may end in mania or melancholia, but even then the case is not hopeless, always. A case under the care of Dr. Charlton Bastian is entitled "Chorea during Pregnancy; semi-maniacal attacks, melancholia; recovery under the use of opium." In this case chloral and the bromides were first used, without avail.

Stated Meeting, May 25, 1888.

The President, Dr. Mary E. Allen, in the chair.

Dr. Rebecca Fleisher presented a paper entitled

Some Facts Concerning the Present Epidemic of Small-Pox in this City,

and said: There is at the present time, as all are no doubt aware, an epidemic of small-pox in this city. The origin of contagious diseases is always interesting, and often instructive, even though the knowledge serves no other end than to demonstrate, over and over again, to a careless community, that the introduction of such diseases is, in almost all cases, preventable, even though their spread is not always so.

It may also stir up public sentiment in favor of increased exertion by health officers and others, that these may have the community supporting them, even if extreme efforts

should seem imperative, in order to meet the end of protection to the city from a great calamity. But it is not only useful as general information and for public use, but the physician sees in the isolated cases, following each other successively, their utter and complete dependence on contagion to induce the disease, and thus, over and over again, is illustrated the characteristic history of epidemics, as to their origin, mode of dissemination, and course.

This epidemic originated from carelessness in not recognizing an eruption possessed by a passenger on board the steamship Lord Clive, from England, arriving here February 1, 1888. This eruption was noticed, but not diagnosticated, before he left the steamer. The passenger obtained board at 2024 Garrett Street, in the southern section of the city, Twenty-sixth Ward; remained there two weeks, and then went West. His soiled clothing was laundried by a woman on Forty-first Street, West Philadelphia, who later became ill with what the physician called *measles;* and it was only after she had been ill for a week that the true nature of the disease was recognized. She was then sent to the Municipal Hospital, where she died March 11. This woman's brother-in-law, living in the same house, had *varioloid;* these were the only persons in this district who were affected. On March 10, a new boarder at 2024 Garrett Street (the house in which the passenger from the Lord Clive lodged) was placed in the bed occupied by the emigrant, no change of bed-clothing having been made; this man became ill and was sent to the hospital. Later another boarder at the same house became ill, but desired to be nursed at his own home on Moyer Street, Thirty-first Ward, in the northern section of the city, and thus carried the disease there.

It was later learned that two other boarders in the Garrett Street house had varioloid, but the cases were not reported at the Health Office.

From March 11 to the 19th, there was no death, but on this latter date a patient from St. Mary's Hospital died.

The rapidity of the spread of the disease was not very great at first, although new cases were reported each day. The course of the spread has been erratic, beginning in the southern, then extending to the western, and then to the northern section of the city. The wards then in turn affected were the Twenty-sixth, Twenty-fourth, Thirty-first, Fourth, Eighteenth, Thirtieth, Third, and so on. The only wards, six in number, until now exempt, are the First, Sixth, Eleventh, Sixteenth, Twenty-first, and Twenty-second. The Second Ward heads the list with thirty reported cases, nine of these being in one house on Temple Street, near Twelfth and Fitzwater. There was no doctor in attendance, and a relative, unconscious of the disease, reported at the Health Office the fact of a boy having been delirious for four days. On a visit to the house, seventeen people were found crowded in three rooms; twelve of the number were sent to the Municipal Hospital, although three of them did not develop the disease. Of the nine who were attacked with small-pox, four died.

The total number of cases reported until within a few days was 176; 81 of these were sent to the hospital; of this latter number, twelve died. Of the 95 treated in their own homes, seventeen died.

Without definite data as to the comparative severity of these two classes of cases, those treated at the hospital and those at home, and with so small a number from which to draw conclusions, it may nevertheless be interesting to note that of those treated in the hospital 14.8 per cent. proved fatal, while of those treated at home 17.8 died. Considering the disadvantages, in a mortality sense, of moving patients ill with any infectious disease, this certainly speaks well for the management of the hospital.

MARY WILLITS, M.D.,
1527 Green Street. *Reporting Secretary.*

PERISCOPE.

Case of Vaginal Lithotomy.

Dr. W. Winterberg, of San Francisco, in a communication to the *Pacific Medical and Surgical Journal*, June, 1888, says that, considering the rare performance of this operation, a detailed account of the following case may not be devoid of interest. Mrs. McM., fifty-two years old, native of New Brunswick, for the last eighteen years a resident of Placer County, Cal., married, had six children at full term, and two miscarriages, following great bodily exertion. The last child was born in 1872. In each case the puerperium was uncomplicated and of short duration. She reached the menopause at the age of forty-six. About six years ago she fell, accidentally striking, with her left side, against a log of wood, and from this fall she dates the beginning of her ailment. She first complained of pain in the region of the left kidney, which would come and go at intervals; then she

began to feel slight inconvenience in micturition. Two years ago she passed a little stone and a quantity of pus and blood; four or five months later there was another discharge of blood and pus, followed by a sensation of great relief to the patient. Afterward she became continually worse, and, being remote from competent medical attendance, did not receive adequate treatment. She finally came to the city April 19, 1888. Dr. Winterberg found her on that day completely exhausted and prostrated by the sufferings she had to endure during her long trip, and unable to leave the bed, since even the slightest motion would make her pains excruciating.

A continuous tremor was shaking her whole body, especially the lower extremities; the pulse was very small and rapid (125), and there was a striking pallor of the face. She complained of great pains in back and loins, and of very frequent micturition, the end of which was always accompanied with unendurable pain. A digital exploration of the vagina proved to be negative in consequence of the enormous thickening of the vesical walls, as was seen later. Being without a sound to explore the bladder, he had to postpone further examination until the following day, when he at once, after the introduction of the sound, discovered the presence of a large calculus. The patient being told that an operation would be necessary, consented without hesitation, and April 22 was fixed for that purpose.

Drs. Foulkes and Kreutzmann assisted, the presence of more assistants being dispensed with by the use of a leg-holder, which keeps the patient in the lithotomy position. One-third of a grain of morphine having been injected hypodermically, the patient was then anæsthetized, the A. C. E. mixture being used. The pulse was very feeble first, but soon rallied under the influence of the morphine. She was placed in the lithotomy position, and an incision was made over a grooved staff through the anterior wall of the vagina, commencing about at the neck of the bladder and extending exactly in the median line for about three inches, when, after the introduction of the finger, the stone could be felt in the fundus of the bladder behind the trigonum, imbedded to over half of its circumference in a diverticulum, and apparently firmly adherent. The adhesions were broken up with the finger, after which it was possible to grasp the stone and extract it with a pair of extracting-forceps.

The longest diameter of the stone was two inches, the longest and shortest circumference being four and one-half to five and one-half inches respectively, and the weight being 900 grains. The bladder was then washed out with a weak solution (1–8000) of bichloride of mercury, and the wound closed up with twelve catgut and six silk sutures; a soft Nélaton catheter was introduced through the urethra into the bladder, and fixed by strips of adhesive plaster for a permanent draining, and about a quart of a three per cent. solution of boric acid used twice a day for washing out the bladder; simultaneously a 1–5000 solution of bichloride of mercury was used for irrigating the vagina twice daily.

The patient was placed in bed with hot bottles to her feet, and she soon recovered consciousness. She declared that she felt greatly relieved, being free from pain for the first time in the last six months. The universal tremor gradually passed away, and she began to gain strength. When Dr. Winterberg saw her on Wednesday morning, the third day after the operation, he learned that the catheter had come out of the bladder the preceding night, after a severe attack of colic, whereby she soon got relief. He found the instrument clogged, and reintroduced it after cleaning it. On examination, he further ascertained that there was no urine passing through the vagina. The bladder would hold now easily four ounces of fluid without distressing the patient. The capacity increased, until two weeks later he could inject twelve ounces without incommoding her. On the eighteenth day of the operation, treatment was discontinued; there being no more symptoms of cystitis, the patient having left the bed at the end of the second week. On the 12th of May, twenty days after the operation, he saw her for the last time; a firm cicatrix had formed over the line of incision; the silk sutures had been removed two weeks before. She felt now strong enough to go to her daughter in Washington Territory.

Dr. Winterberg remarks that the principal point of interest connected with this case is the rarity of stone in women. Klien, in the Moscow City Hospital, found, in 1,792 cases of stone in the bladder, only four (4) in females; M. Lett did lithotomy 106 times in men and only once in a woman during a period of fifty-seven years; I. Winkel found, amongst 10,000 female patients examined by him during a period of twenty-four years (1860–84), only one affected with stone. As to the various methods of operating for stone in females,

colpocystotomy certainly will be the most eligible one in all those cases in which a bloody operation is necessitated by the size of the stone in adult females; while in children, epicystotomy would be the proper method in a number of cases, if the stone were too large for extraction through the pelvis without injuring the soft tissues. The vagino-vesical operation was performed the first time by Fabricius Hildanus (in 1628), and his example has been imitated repeatedly by different operators.

There is no risk, he says, of producing a vesico-vaginal fistula by this operation, if the wound be properly closed by careful coaptation and suturing. The material he would select for suturing in future cases would be catgut; that it will certainly resist absorption until union has taken place is shown by the present case; the edges of the wound had been agglutinated firmly enough on the third day to resist a pressure strong enough to force out the catheter, which had been attached quite securely to the neighboring parts by means of several strips of rubber plaster.

As to the use of the permanent catheter, he thinks it will be extremely beneficial in a case like this, where there was an immense thickening of the vesical walls. By its employment the organ is entirely set at rest, and consequently atrophy of the thickened tissues will take place; besides that, the urine, being drained off as soon as it enters the bladder, has no time to be decomposed or act as an irritant, and the presence of a soft Nélaton catheter will not cause any trouble whatever, provided it be cleaned at least once in two days.

Tumor of the Spinal Cord; Removal; Recovery.

At the meeting of the Royal Medico-Chirurgical Society, June 12, 1888, Dr. Gowers gave in detail the medical history of this case (which has already been referred to in the Reporter, February 18, 1888). The patient was a man, forty-two years old, who had suffered for three years with localized pain beneath the lower part of the left scapula. The pain varied much; at times it was scarcely felt, at other times it was most intense, and then was increased by movement to such a degree as to render it impossible for the patient to walk. Many medical men were consulted, and the diagnosis varied between aneurism and neuralgia. Hypochondriacal insanity was even suggested, on account of the irritability of the patient, whose mind almost gave way under the continued suffering. Four months before the operation, first the left and then the right leg became weak, and the loss of power gradually increased to complete paraplegia. The patient was first seen by Dr. Gowers, with Dr. Percy Kidd, on June 4, 1887. There was then motor and sensory paralysis up to the level of the sixth or seventh dorsal nerves, with intense spasm in the legs, foot clonus, and rectus clonus. The urine was retained, and there was some cystitis. At the level of the sixth dorsal nerves there was severe pain around the trunk, greater on the left side, and increased to agony by any movement. The symptoms pointed clearly to compression of the cord by a morbid process outside it. Caries of the spine could be practically excluded; aneurism was improbable, although not impossible. The diagnosis lay chiefly between a tumor of the spinal bones and a tumor of the membrane. The indications (described in the paper) made a meningeal tumor rather the more probable. Syphilitic disease could be excluded. An operation afforded the only chance of escape from certain death after intense suffering. Sir William Jenner saw the patient, and concurred in the diagnosis, and sanctioned an operation. The patient was aware of the uncertainty of the result, but was extremely anxious that something should be done.

The surgical history of the case was read by Mr. Horsley. The diagnosis of intra-dural tumor pressing on the cord appearing to be well founded, an operation was performed for its removal on June 9. Mr. Victor Horsley laid bare the spinal column from the third to the seventh dorsal vertebræ, and cut off the fourth, fifth, and sixth spinous processes with strong bone-forceps. He made his way through the laminæ on both sides, and the still more obstinate ligamenta subflava, slit the dura mater up the middle line, and laid bare the spinal cord. When the opening was first made the injury had been suspected, but the tissues were healthy. That the attempt should be abandoned was counseled by some, but Mr. Horsley preferred to complete his task, and removed the posterior part of another superior vertebra, and there found a tumor of the dura mater compressing the cord. It could easily be shelled out of its deep bed; the wound was carefully closed and drained, and it healed by first intention. The patient gradually lost the agonizing pain, and at the same time gradually recovered motor and sensory power, as well as control over the

bladder and rectum. He remains in perfect health. Appended to the surgical history of the case are a table and analysis, in which the chief clinical facts relating to fifty-seven other cases are recorded. From the latter it appears that operation is the only treatment to be adopted in such cases, and that, if it had been resorted to, 80 per cent. should have recovered, whereas all died.—*British Med. Journal*, June 16, 1888.

Hemiplegia Occurring Nine Days After Parturition.

At the meeting of the Obstetrical Society of London, May 2, 1888, Dr. E. F. Scougal reported a case in which a patient, 37 years old, was confined on August 21, 1887, of her seventh child. All went well till August 28, when she complained of numbness and tingling in the first, second, and third fingers of the left hand. At 1.30 A.M. on August 29, the nurse noticed that, amongst other symptoms, the patient's mouth was slightly drawn to the right. At 3.30 P.M. she was found as follows: Complete paralysis of the left arm and paresis of the left leg; slight divergent strabismus of the right eye, and the mouth slightly drawn to the right side. There had been a little difficulty in swallowing, which had now passed away. Consciousness and speech were unaffected; there was some pain on the right side of the head. The skin was moist, temperature normal, pulse 96; no loss of sensation could be detected. Three and a half grains of calomel in pill were given, to be followed by two ounces of Æsculap water every two hours till catharsis was produced, and a draught containing iodide of potassium and citrate of potash was prescribed. By 1 P.M. the left leg was completely paralyzed. In the course of the next day, drowsiness came on, the bowels were opened by enemata; later on, restlessness and increased pain in the right side of the head were observed, the temperature rose to 99.2°; the pulse was irregular in rhythm and power, varying from 72 to 84. The secretion of milk had quite disappeared by August 31. The patient became comatose, and died at 2.15 on September 1. The brain alone was examined after death. A clot was found in a vein on the surface of the brain, corresponding in position to the right middle meningeal artery, and another in a vein corresponding in position to the right middle cerebral artery. These clots were distinctly *ante-mortem*. There was no sign of thrombi in the sinuses. The brain, pons, and medulla exhibited no trace of extravasations, or of any other morbid appearance.

In discussing the case, Dr. Leith Napier remarked that puerperal hemiplegia was practically due to thrombosis, embolism, or reflex influences; the first cause being the most frequent.—*American Journal of Obstetrics*, July, 1888.

Sudden Death from Distention of the Stomach.

Dr. M. A. Veeder, of Lyons, N. Y., writes to the *Medical Record*, July 14, 1888, that he saw recently an example of sudden death from a cause that is probably quite uncommon. The patient, a woman in middle life, was subject to dyspeptic symptoms, at times suffering greatly with gastralgia; otherwise her health was good. On the day of her death, she was apparently as well as usual, and ate a very hearty dinner. Rising from the table, she went into the garden to feed some chickens. In less than three minutes, she was found by her husband, who followed her, sitting upon a step, dead. At the post-mortem examination, within twenty-four hours, it was found that the stomach was very large, and had been distended, not only by the hearty meal, but also with a considerable volume of gas. The heart was compressed so effectually by the distended stomach that its walls were in contact with each other, and it did not contain more than a few drops of blood. Careful examination, he says, failed to reveal any other cause of death than this stoppage of the circulation, which must have been instantaneous and complete.

Use of Cold in Summer Diarrhœas of Children.

With reference to the use of cold in the summer diarrhœas of children, the *Therapeutic Gazette*, July, 1888, remarks: "As the heated term is upon us, we take the liberty of calling the attention of our readers to a practice concerning which we have frequently written, but which we do not think obtains among the profession as largely as it ought to. Anyone who watches the mortality-lists of our large cities knows that any marked ascent of the average heat-record of the thermometer is accompanied by a corresponding rise in the mortality-list; also that the rise is chiefly made up of infantile deaths, such deaths in turn being in great part the result of some form of diarrhœa. Whether these cases are called cholera infantum, or summer diarrhœa, or

enteritis, or colitis, we believe that they are in great part the direct result of overheating of the body, and that they are to be best combated by the use of the cold bath. In all such cases, the physician should take the temperature of the little patient, and if, as is generally the case, the bodily heat is distinctly above normal, systematic cold bathing should be enforced. It may be necessary to give the cold bath every two hours; it may only be required three times in the twenty-four hours. At first, the child usually resists the bath violently, and the prejudices of the mother often are like the wall of a fortification; but, whenever we have persevered, the results have been so marked as not only rapidly to overcome the prejudice of the mother, but also to teach the child itself the value of the bath and cause the outcries and resistance on its part to cease entirely. We wish that this treatment would be fairly tried by our readers, and reports made thereon through our columns."

Terpine in Diseases of the Lungs.

Dr. D. M. Cammann, in a paper read before the Section on Materia Medica and Therapeutics of the New York Academy of Medicine (*Medical Record*, June 30, 1888), says that terpine is a crystalline hydrate of the oil of turpentine. Crystals similar, if not identical in character, have been found in the interior of an old pine-log, where they were probably formed from the oil deposited in the wood. If oil of turpentine be allowed to stand for some time freely exposed to the air and to moisture, crystals of terpine will be deposited on the sides of the vessel. It is colorless, odorless, and almost tasteless, insoluble in water, soluble in alcohol, and melts at 212° F. It was first prescribed as an expectorant by Lépine, of Lyons, who calls it "the best expectorant in existence." Its use in bronchial affections has been favorably mentioned by Vigier, Jeannel, Sée, and Boyland. New drugs are apt, he says, to be received with enthusiasm, to run a brief course, and then to drop out of use. Terpine has not escaped the usual fate at the outset of its career, but that it is a drug that deserves a permanent place seems probable. During the past year, Dr. Cammann has frequently used terpine in his class at the Demilt Dispensary and elsewhere, and a careful record of a number of cases has been kept by Dr. F. N. Patterson.

After giving short histories of a few of the cases, he says an analysis of twenty-five cases shows that nineteen were cases of bronchitis, most of them chronic, some of them of long standing, with extensive pleuritic adhesions. Four cases were of phthisis, one of pleurisy, and one of emphysema. The shortest time that any of these cases was under treatment was two days, the longest time nine weeks. The average length of treatment was seventeen days. From four to eight grains of the terpine were given in pills, usually four times daily. Most of the cases took four grains four times daily, without any other drug. Twenty-four of the cases were improved, most of them markedly, and two only slightly. One case was unimproved. This was a case of bronchitis that had lasted a month, and four grains of the terpine were given three times daily for five days. The expectoration became thinner, but no other change was apparent. The cough, he says, was lessened in all the cases except the one just mentioned. In twenty of the twenty-five cases the expectoration was markedly diminished; in four it was not diminished, and in one it was increased. In several cases it was increased for the first day or two, and afterward decreased. The cases in which the expectoration is recorded as not diminished, and the one in which it was increased, were under observation only five or six days, and it is probable that if they had been treated longer a diminution might have been recorded in all. In eighteen it was thinner, becoming more watery and less purulent; in six it was no thinner. Of the cases that were troubled with dyspnœa, the dyspnœa was diminished in sixteen; it was undiminished in three. The patients noticed an increase in the urine in eleven cases; in eleven cases no increase was noticed. In some of the cases the appetite improved; in one case slight nausea, and in another fulness of the head, were experienced after taking the pills.

The mode of action of turpentine and its derivations, he thinks, needs further investigation. That they are cardiac stimulants has been asserted, probably on insufficient evidence. The experiments of Nothnagel and Rossbach indicate that oil of turpentine in all cases diminishes the blood-pressure, and to a very slight degree, or not at all, the number of cardiac pulsations. Whether they enter into the circulation unchanged or not is uncertain. Whether the peroxide of hydrogen, which some of the terebinthinates, in common with many other substances, are capable of generating and then absorbing, plays an important part in their action, he thinks is a subject for further study.

Foreign Body in the Male Bladder.

G. Buckston Browne, in a letter to the *British Med. Journal*, June 30, 1888, says that a man was sent to him by Dr. Miller on May 19, 1887, with the following history: The patient said that, several years ago, he had been told by a medical man that, if there was ever any difficulty in micturition, a paraffine candle was to be warmed, molded into the form of a bougie, and passed into the urethra. Six weeks before seeing Mr. Browne, having some slight irritation, these manœuvres were practiced; but, on attempting to remove the paraffine bougie from the body, little more came away than was actually held between the fingers. Since then, he had become more and more uncomfortable; the movements of a cab or carriage could not be borne, and he could walk only very slowly. He felt as if "he had a marble in his bladder." The bladder had been sounded and nothing found, and he complained that several surgeons had been incredulous of his story. He was nervous, and in so much pain that Mr. Browne declined to do anything until he was in bed. Mr. Charles Moss administered ether, and Mr. H. S. Byam, of Chester Square, assisted. A wax-like body was at once found in the bladder, and seized with a lithotrite with some hesitation, because there was no means of knowing exactly what had to be dealt with, and Mr. Browne was anxious not to bite into a sticky mass from which the jaws of the instrument might not readily be extricated. However, during its six weeks' sojourn in the bladder, the wax had become incorporated with a good deal of phosphatic matter; it crumbled rather than broke, and very soon nothing of any size remained to be seized with the lithotrite. An ordinary lithotrity evacuating-tube was then introduced, but only a small amount of *débris* could be extracted, for it was so light that the bulk of it refused to be drawn into the aspirator. The lithotrite was therefore again introduced into an almost empty bladder; and a good deal of waxy matter, which burnt with a flame when applied to a lighted candle, was withdrawn between the blades of the instrument; the rest was well broken up, and the operation completed. The patient being a comparatively young man, it was thought that almost all might now be left to nature, and, for about two or three weeks, not a day passed without some paraffine coming away, either naturally or by the use of a soft catheter and an india-rubber washing-bottle. On June 19, 1887, he passed the last piece, and on the same day was the winner at putting the shot and throwing the hammer, at some athletic sports. He has continued perfectly well ever since.

Tuberculosis Transmitted by the Milk of a Phthisical Cow.

A remarkable case has been recorded by Denune, of Berne, in which an infant became infected with tuberculosis through the milk which had been obtained from a phthisical cow. The details of the case are as follow: An infant, four months old, belonging to a family whose history was absolutely negative in regard to tubercular affections, died of tuberculosis of the mesenteric glands, a fact which was confirmed at the post-mortem examination. The glands alone contained the characteristic bacilli; the latter were not even to be detected in the intestinal mucous membrane, and no bacilli were found in any other part of the body. The child was fed with the milk of a cow which was especially kept for the purpose. The cow, for the purposes of examination and inquiry, was slaughtered, and a careful post-mortem made of its carcass. The left lung and pleura of the animal were found to be studded with tubercle, and, in the tubercular nodules, bacilli were easily found. The milk was then submitted to a minute investigation, but bacteriological examination at first yielded negative results. Finally, however, tubercle bacilli were detected in portions of the liquid expressed from the deepest parts of the mammary gland. The case is an important one from several points of view, and claims attention by reason of its bearing upon the so-called hereditary transmission of tuberculosis. If, instead of a human infant, a calf had in a natural manner fed itself with milk from its mother's udders, we can hardly conceive otherwise than that the calf would have similarly become infected with tubercle. Assuming such to have occurred, the case would obviously have been regarded as one of the hereditary transmission of tubercle. But, taking the supposition that a woman suffering from phthisis suckles an infant, there seems to be no reason why the same result should not occur, and why, like the infant and the cow to which reference has been made, the mother should not transmit the bacilli, by means of her milk, to her offspring. All this appears to be possible enough, and has, perhaps, even occurred in some cases without the fact having been proved by demonstration.—*Medical Press and Circular*, June 27, 1888.

Action of the Vagus Upon the Secretion of Urine.

J. B. Masius (*Extrait des Bulletins de l'Académie royale de Belgique*, No. 3, 1888) confirms the facts ascertained by Arthraud and Butte that, after sufficiently strong electrical irritation of the peripheral end of the previously severed right vagus, the secretion of urine diminishes and becomes entirely retained, while the urine which is passed contains albumin, blood-corpuscles, and epithelial cells. Masius finds, in addition, that the left vagus behaves in like manner. This phenomenon is explained by the further observation that, while electrical irritation increases the pressure with which the blood flows out of the renal veins, after injection of atropine, which paralyzes the inhibitory fibres of the heart and vaso-constrictor fibres of the kidney which come from the vagus, neither secretion of urine nor discharge of blood from the renal veins is modified. The changes in secretion of urine are, therefore, brought about by constriction of the arteries of the kidney.—*Centralblatt f. d. med. Wissenschaften*, June 2, 1888.

Unusual Foreign Body in the Larynx.

A recent number of the *Revue de Médecine et de Pharmacie militaire* contains an account of an extraordinary case, in which a leech, that had somehow found its way into a man's larynx without his knowledge, gave rise to unpleasant symptoms, for which the medical attendants were puzzled to assign a cause. The patient, a soldier, had suffered for three weeks from hoarseness and a sensation as of a foreign body in the larynx, but there was no serious dyspnœa, and nothing could be seen with the laryngoscope. During the last eight days of that time, he spat blood, and at length he distinctly felt something move deep down in his throat. On the twenty-third day, after the patient had made a violent expiratory effort, Dr. Godet caught sight of the leech fixed in the subglottic part of the larynx. No proper laryngeal forceps being at hand, the thyroid cartilage was divided in the middle line in front; on separating the two halves, the leech was easily removed. Two sutures were inserted, and perfect union was obtained. The voice was absolutely unaffected by the operation, a point worth noting in view of the great stress that has recently been laid on the serious impairment of the vocal function which thyrotomy is supposed to entail. One would like to know how the unwelcome guest managed to get into the man's throat without his being aware of the fact. It is possible that he swallowed it in drinking water out of a ditch or pond.—*British Medical Journal*, July 7, 1888.

Antipyrine in Rheumatic Chorea.

It is a very difficult for a practitioner to form an opinion as to the value of a new remedy. In many cases, experience has proved that the eulogistic claims of introducers of such remedies have to be greatly discounted before a correct estimate can be formed. At present, antipyrine is the fashion. But even now it is difficult to correctly estimate its value as an antiseptic, analgesic, antipyretic, and antirheumatic. In an article published in *La France Médicale*, No. 14, 1888, Dr. B. Boussi confirms Legroux's statement as to the value of this drug in chorea, and calls further attention to this employment of antipyrine. Dr. Boussi states that he was called to see a child eight years of age, the son of a workman, whom he found in a state of high fever, complaining of pain in the throat and headache. The preceding day, he had had an eruption, which had, however, disappeared when seen by Dr. Boussi. The probable diagnosis of scarlatina was made, but a few days later the case developed into an acute articular rheumatism, accompanied with endocarditis. Thirty grains of salicylate of sodium were given daily, and cure resulted in eight or ten days. At this time, a pronounced desquamation confirmed the diagnosis of scarlatina. Five or six days later, after the cure of the rheumatism, the child commenced to suffer from disordered movements, which became more and more violent, until in ten days chorea of the gravest character was developed. Treatment was then commenced with thirty grains of antipyrine given in four doses daily in a little sugar and water. On the very next day, improvement was evident, sleep was possible without disturbance by choreic movements, and in two days, after the administration of sixty grains of antipyrine, the choreiform movements had almost entirely disappeared. In all, the treatment had lasted but eight days, during which time the chorea was practically cured, the patient having taken in all but little more than half an ounce of antipyrine. Dr. Boussi's results encourage an extended trial of antipyrine in chorea.—*Therapeutic Gazette*, July, 1888.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

QUACK ADVERTISEMENTS IN RELIGIOUS NEWSPAPERS.

When a wrong is assailed in general terms, the assault is apt to be interesting to those who participate in it, and perhaps to those who witness it; but there is some danger that it may not accomplish very much. This truth is illustrated by the results which have so far followed the attempts of various medical journals in this country to abate the evil of quack advertisements in religious newspapers. These attempts have been approved and applauded by medical men, and those who made them knew they were discharging a useful office. But the religious newspapers have not been cured; and, indeed, they do not seem to have improved materially.

One of the reasons for this is, no doubt, the fact that the attack has not been sufficiently sharp on any portion of the line to break it, and that, while the whole religious press bore the brunt of the assault, no one part experienced any special inconvenience from it.

What is now needed, we believe, is that the force of public opinion should be concentrated upon conspicuous offenders, and that an attempt should be made to compel them to regard the principles of honor and decency which they have so long violated. This is a method which is far from pleasant, but it is our honest opinion that no kindlier one will effect the object.

That our readers may understand why we say this, we inform them that we took the trouble to send our Editorial of December 31, 1887—which we intended to be temperate, though plain-spoken—to the editor of almost every religious paper in the United States, and that by personal correspondence we have endeavored to enlist the self-respecting religious papers on the side of right in this matter. Some good has been accomplished. A few of the religious papers have expressed themselves as we hoped they would. More than this, a number of our medical contemporaries have added their efforts to ours, while the Medical Society of the State of Arkansas has issued a series of resolutions against the evil of false and misleading advertisements in religious newspapers, and these resolutions have been approved and endorsed by the American Medical Association.

We were glad to note, also, in the REPORTER, June 9, 1888, that a representative religious body—the General Assembly of the Presbyterian Church—at its last meeting, in Philadelphia, received, and, we believe, endorsed, an overture of a like character.

This much is cause for thankfulness. But much more remains to be done. How much, may be judged from the fact that, in spite of all we have said, one of the most influential Presbyterian papers in the land persistently continues to publish advertisements

which any man of common sense would know to be absolutely and unblushingly false. In a recent issue of this paper, there were no less than seven advertisements which deserve to be characterized in this way, including sure cures for deafness, cancer, fits, and consumption! And the difficulty of dealing with cases of this kind may be estimated when we state that the editor of the REPORTER has made a special attempt, by writing personally to the editor, who is also the owner, of the paper referred to, to induce him to correct the wrong he was committing.

Another illustration is furnished by one of the representative papers of the Methodist Church—a paper which is, we believe, directly governed by the ruling body of that church. The *St. Joseph Medical Herald*, in May, 1888, speaking on this subject, says that this paper "sells the columns which should be filled with religious matter to the vilest impostors and most indecent advertisements of which the country can boast." This is strong language; but it is fully warranted by the circumstances.

We appreciate the good work done by religious papers, and it is for this reason that we wish to see them freed from a reproach which interferes with their usefulness and injures the cause of religion. We have tried to bring this about in a way which should not give needless offense. But, as we believe that no reform is ever accomplished without somebody being hurt, we shall not hesitate, when next we take this subject up, to lay our hands on particular religious papers and say plainly to the editor of each: "Thou art the man!"

We do not now take this step, because we hope that some to whom this charge would apply to-day will clear themselves before the time arrives to make it.

We beg our medical contemporaries to join their efforts to ours to cure this evil as gently as may be possible, but with all the firmness that may be necessary; and we beg our religious contemporaries to make our cause their own, so that we may seem rather to offer counsel to those who wish to know what is right, than to formulate censure against those who choose to do what is wrong. Physicians and the clergy are usually sympathetic with, and helpful to, each other; and it would be a pity if the religious papers were to maintain an attitude which invites the distrust and—it must be said—the contempt of those who should be their best friends.

TREATMENT OF PNEUMONIA WITH TARTAR EMETIC.

On several occasions during the twelve months just past, we have laid before our readers articles on the treatment of pneumonia, which directed attention to the usefulness of methods which have gone out of fashion, so to speak. It is interesting, therefore, to note that in Germany, of late, the merits of tartar emetic have been discussed and warmly advocated. In the *Deutsche med. Wochenschrift* for 1887, No. 47, there was a paper by Mosler which accorded an important rôle to this agent; and in the number for May 31, 1888, a similar position is taken, founded largely upon the experience of BRÜCKNER, who says that, in his opinion, there is no better remedy in the treatment of pneumonia in young and vigorous individuals, and that it may be regarded as almost a specific. He began its use at the suggestion of an intelligent practitioner, who declared that he had never had such good results from the use of any other remedy or measures. Brückner began the use of tartar emetic with decided misgiving, but soon became convinced of its great value. He reports the case of a young man with acute croupous pneumonia, to whom he gave, at the outset, a tablespoonful of a solution of one part of tartar emetic in five hundred parts of water. The patient soon vomited, and a dose of the solution was then given every two hours. In twenty-four hours, the patient had vomited four times, but was decidedly better, and in

five days his temperature was nearly normal, and his pneumonia in a state which left no room for anxiety. In his present practice, Brückner uses a solution of from one to three parts in two thousand parts of water, giving a tablespoonful every hour until vomiting or catharsis occurs, after which the dose is given every two hours. He has usually observed vomiting after the first or second dose. This is followed by from four to eight watery stools, sweating, and freer expectoration.

The beneficial results of this method in the treatment of seventy or eighty patients have been so striking that Brückner is quite enthusiastic over them. He has not found these results in every case so treated, but in the great majority of his cases he has seen great improvement to occur.

These results certainly warrant careful study in this country, where tartar emetic is not unappreciated, but where its administration in pneumonia is by no means common. There was a time when almost all cases of frank pneumonia were treated with bleeding and tartar emetic. But the time has passed away, and it is worth while to emphasize the claims advanced by Brückner, and to direct attention again to this valuable remedy.

BABY FARMS.

Under the euphemistic title of "Private Nurseries in New York," attention has been called in the daily papers to the extent to which baby farming is carried out in that city. So much complaint has been made in regard to these establishments in New York, that the Society for the Prevention of Cruelty to Children has decided to investigate and watch them. A special department is to be established, with inspectors who shall frequently and carefully investigate all the so-called nurseries now licensed, and an attempt will be made to suppress any that are conducted in violation of law. It is good to see that influential society has decided to make an attempt to root out an institution which commits some of the most outrageous cruelties that are permitted in this day. Probably many medical men living in large cities have their attention from time to time directed to what are called "Baby Farms." Not unfrequently a medical man is summoned out of his ordinary line of practice to see some wretched child about to die, whose care-takers desire of him nothing except a certificate of death, which shall save them from the investigations of the coroner. It is probable, also, that, under these circumstances, medical men, although moved to pity for the sufferer about to die, seldom think that it may be a public duty to call the attention of the authorities to the establishment in which the occurrence is about to take place; and yet there can be no doubt that it is a public duty, and that the conscientious discharge of this duty by physicians, no matter how troublesome, disagreeable, or unkind it may seem, would do more to put an end to the errors and atrocities of baby farming than all the investigations which could be carried out by any organized society. In New York, where the society mentioned is undertaking the work, we trust that the physicians will give it their hearty co-operation; and in other cities, where the work has not yet been so undertaken, we believe that physicians might suggest, to any similar society, the propriety of taking hold of it.

ANOTHER MEDICAL AND SURGICAL REPORTER.

In our issue of July 28, we called attention to the appearance of a new medical journal which had taken the name of this one. Assuming that this was an error not inconsistent with honest intentions, we expressed the hope that it would soon be corrected. Since then, however, the second number of that publication has appeared, bearing the title: THE TOLEDO MEDICAL AND SURGICAL REPORTER — the first two words printed small, and the part of the title which copies ours printed in large letters. This step on the

part of the publishers, we think, justifies the belief that they hope to profit by assuming our name, and are not to be deterred from it by those principles which actuate honorable men. We trust that our contemporaries, for the sake of the guild, will treat this appropriation of our title as it should be treated, and support us in endeavoring to maintain our exclusive right to the title which the MEDICAL AND SURGICAL REPORTER has borne for more than thirty years.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

COMPARATIVE STUDIES OF MAMMALIAN BLOOD, WITH SPECIAL REFERENCE TO THE MICROSCOPICAL DIAGNOSIS OF BLOOD-STAINS IN CRIMINAL CASES. BY HENRY F. FORMAD, B.M., M.D., Lecturer on Experimental Pathology, etc., in the University of Pennsylvania, etc., with sixteen illustrations from photo-micrographs and drawings. 8vo, pp. 61. Philadelphia: A. L. Hummel, M.D., publisher, 1888.

Dr. Formad, in this interesting monograph, lays down a principle which is of the utmost importance in hæmatology and in medical jurisprudence, namely, that it is possible by measurement of blood-corpuscles to determine whether or not they are those of a human being. This principle he defends by an argument founded upon an unusually large experience in the study of histology and in the trial of persons charged with murder. It is well known that he has encountered opposition, and even censure, for acting upon the beliefs expressed in this book in certain trials, and many who have felt that it was prudent to suspend their judgment as to the merits of the case until they had more facts to guide them will welcome his explanation of the grounds for his belief, especially as it seems to be a complete vindication of his actions. There seems to be little room for doubt that he is right in claiming that it is possible, in a reasonable sense, for one expert in the study of blood-corpuscles to say that such as come under notice in murder-trials are, or are not, human. The objections to this view appear to us to be captious; and we do not find anything in it, as put by Dr. Formad, to warrant the severe criticisms to which he has been subjected.

The book before us is sure of attracting much attention, and we think it a very valuable addition to the literature of medical jurisprudence. It is pleasant to note in it that full justice is done to the work of the late Dr. Joseph G. Richardson, of this city, whose skilful and careful measurements of blood-corpuscles were among the most valuable contributions to science.

PRACTICAL ELECTRO-THERAPEUTICS. BY WILLIAM F. HUTCHINSON, M.D. 8vo, pp. 247. Philadelphia: Records, McMullin & Co., 1888.

This book has been written with the object of explaining the indications for and methods of employing electricity in medical and surgical practice in such a simple way that it shall not be beyond the comprehension or opportunities of the average practitioner. This object has been, we think, very well attained. The author describes only such electrical apparatus as can be used by every intelligent medical man, and omits from his work all of those abstruse and elaborate matters in regard to electricity which encumber most systematic treatises on medical electricity. This he does—not because he does not appreciate the scientific value of these matters—but because he appreciates equally that they are not essential to a successful employment of this agent in actual practice. His book is not one for the accomplished student of electricity; but it is one eminently suited to the needs of those who stumble at too much discussion of "ohms" and ampères, but wish to be told in the briefest and most intelligible terms how they may employ electricity in treating disease.

We think the author might have gone a little further in illustrating the book, without disadvantage; but are glad to be able to recommend his work as clear and comprehensible, and, in our opinion, calculated to be very useful.

PAMPHLET NOTICES.

[Any reader of the REPORTER who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

THE EXTRACTION OF CATARACT AS INFLUENCED BY MYCOLOGICAL DEVELOPMENT. BY A. E. PRINCE, M.D., Jacksonville, Ill. 4 pages.

FOOD LAWS. A PAPER READ BEFORE THE MEDICAL JURISPRUDENCE SOCIETY OF PHILADELPHIA, MARCH 13, 1888. BY HENRY LEFFMANN, M.D. Philadelphia: Published by the Society. 7 pages.

CLINICAL NOTES ON PRURITUS. BY L. DUNCAN BULKLEY, A.M., M.D., New York. From the *Journal of Cutaneous and Genito-Urinary Diseases*, December, 1887. 14 pages.

THE DRINK EVIL. THE PHYSICIAN'S RELATION TO THE LIQUOR QUESTION. A lecture before the Lincoln Medical Society, April 10, 1888. BY A. S VON MANSFELDE, M.D., Ashland, Neb. From the *Daily Nebraska State Journal*, April 15, 1888. 8 pages.

—Dr. Prince's short article is not a systematic study of the subject indicated in its title, but a description of the method he adopts in operating for cataract, with a brief introductory statement of the opinion that suppuration is due to the action of microbes.

—We can heartily commend Dr. Leffmann's pamphlet to the attention of our readers. It deals in a sensible and temperate way with one of the most important questions of medical jurisprudence, and public sanitation. It is agreeable to find that the author holds views, in regard to this matter, similar to those of the REPORTER, and we wish they might have the careful attention of all medical men and all legislators.

—Dr. Bulkley's pamphlet contains a clear statement of the condition which is designated as pruritus by the dermatologists, illustrated by brief accounts of a number of cases occurring in his practice. One of the most interesting parts of his paper is that in which he describes his study of the symptom of itch-

ing as occurring in his own person, and its reflex relation to certain causes of irritation.

—Dr. von Mansfelde, in his lecture, presents what may be called the "temperance" view of the alcohol question, as contrasted with the "total abstinence" view. He studies the nature and effects of alcoholic beverages in sickness and in health, and expresses the opinion that they may be used with propriety in both states, although their abuse is dangerous. He acknowledges that in the state of health there is no need for the use of alcohol, but sees some advantage in its bracing influence in conditions of mental or physical depression.

In sickness, he believes great benefit may be derived from the use of alcohol as a medicine, and charges with fanaticism those who would forbid it entirely. His views are supported by quotations from the writings of eminent practitioners and observers, and deserve the thoughtful attention of all who are open to reason in a matter which is naturally so full of appeals to prejudice.

CORRESPONDENCE.

Typhoid Fever and Chorea.

We recently received a letter from one of our subscribers asking for the opinions of Drs. William Pepper, H. C. Wood, and Wharton Sinkler in answer to the question: "Is Typhoid Fever, Complicated with Acute Chorea, Necessarily Fatal?" In response to a request sent to these men, the following answers have been received, which we take pleasure in publishing.

TO THE EDITOR.

Sir: In reply to the question whether or not typhoid fever, complicated with acute chorea, is necessarily fatal, I would observe that cases of this fever, exhibiting any nervous symptom carried to a very high degree, are of unfavorable prognosis. This applies to ataxic phenomena as much as to any others. Mere jactitation, highly marked subsultus, and the like, are often met with in cases which, though severe, terminate in recovery. But, when the ataxia reaches a point at which the term acute chorea would become applicable, it indicates extreme danger. Without saying that such cases are necessarily fatal—for such a sweeping assertion can be made with reference to no symptom whatever—it must be admitted that they usually end fatally, and that this symptom (so-called acute chorea) is of most serious significance. Yours truly,

WILLIAM PEPPER.

1811 Spruce Street,
July 31, 1888.

TO THE EDITOR.

Sir: In answer to your letter of July 23, I would reply to question—"Is Typhoid Fever, complicated with Acute Chorea, necessarily Fatal?"—no.

Yours truly, H. C. WOOD.

Jewell's Island, Maine,
July 30, 1888.

TO THE EDITOR.

Sir: There is no reason why typhoid fever, complicated with acute chorea, should necessarily be fatal. If the attack of typhoid fever be severe and the choreic movements be general and violent, then the patient's condition would, of course, be more grave, and the chances of recovery diminished. Dr. Hunt has reported a case of fracture in patient suffering from chronic chorea where death ensued from exhaustion, owing to the fact that the fracture could not be held in position by any splint or dressing.

Yours truly, WHARTON SINKLER.

1534 Pine Street, Philadelphia,
July 24, 1888.

Solvent for Salol.

TO THE EDITOR.

Sir: Will you please give me, through the REPORTER, a solvent for the new preparation, salol? What literature I have on the subject does not give the mode of administration.

Cold water does not dissolve it at all; alcohol leaves a crystalline precipitate; and hot water separates the two ingredients and leaves the carbolic acid free.

The information will oblige an appreciative reader of the REPORTER.

S. H. BARHAM, M.D.

Lone Oak, Texas,
August 1, 1888.

[Salol is easily soluble in alcohol with the application of heat, and is entirely soluble in ether and benzine. For internal use, however, it is best administered in compressed pill, capsule, or wafer.

Ewald gives the following formula for a mouth-wash:

Salol	gr. xv
Alcohol	ʒ iii
Tincture of cochineal	♏ lxxv
Oil of rose	gtt. i
Oil of mint	gtt. ii

M. Sig. Add a teaspoonful to a glass of water, and use as a wash. EDITOR REPORTER.]

Ipecacuanha Spray in Throat Cough.

TO THE EDITOR.

Sir: Please explain fully the method and form of remedy employed in treatment of throat cough by ipecacuanha spray. I have a patient upon whom I wish to use it at once. Yours truly,

H. L. MANCHESTER.

Parrlet, Vt.,
August 7, 1888.

[Dr. William Murrell, of London, employs the wine of ipecacuanha in the form of a spray in bronchitis and winter cough. Either a hand-ball apparatus or a small steam atomizer may be used, but the spray must be warm, and the patient should be protected from exposure afterward. The vapor should actually enter the lungs, and not be stopped by the palate and root of the tongue. Dr. Murrell says the best results are obtained by using the spray for about ten minutes three or four times a day, for a week or more. The wine of ipecacuanha may be employed pure, or diluted with water, as the requirements of the case may seem to demand. EDITOR REPORTER.]

Notes and Comments.

Caffeine as a Cardiac Stimulant.

In a communication on the use of the double salt of caffeine (caffeine sodium salicylate) in diseases of the lung (*Berliner klin. Wochenschrift*, June 18, 25, 1888), Dr. Te Gempt states that the drug is indicated in the course of acute fibrinous pneumonia as soon as there is evidence of heart-failure, lowering of the arterial pressure, and an abnormal frequency or an irregularity of the pulse. The administration of the drug should be begun, if possible, before the appearance of symptoms of collapse; while, in a sudden occurrence of the latter, caffeine is all the more urgently needed and its use is often of service. In conditions of cardiac weakness, failure, and atrophy, and also in drunkards and old men, its use from the very beginning is advised. When rightly used and in the proper doses, it effects a diminution in the frequency of the pulse and respiration, an increase in the arterial pressure, a lowering of the temperature, and a favorable influence upon the general feeling of the patient. Stimulants are not to be withheld, but are to be used, when indicated, along with the caffeine. The action of caffeine is rapid, and can be made more rapid and certain in threatening cases by giving it hypodermically. Its use may be continued for a short time after the subsidence of the pyrexia. Caffeine is indicated in conditions of atelectasis or hypostasis of the lungs; and its use in emphysema and asthma is analogous to its use in diseases of the heart

Electrolysis in Stricture of the Urethra.

Dr. T. H. Burchard, in a communication to the *Medical Record*, June 16, 1888, gives his unqualified approval to the following propositions previously formulated by Dr. William T. Belfield:

"1. It is applicable to stricture in any point of the urethra.

"2. Any stricture or succession of strictures, however rigid and cartilaginous, however long and tortuous, however tight, even if impermeable, can be readily and safely perforated.

"3. As a rule, it causes no pain or bleeding, is followed by no chill or urethral fever, and is always devoid of danger.

"4. When properly performed, it can produce no false passage or other local lesions.

"5. The effects are more enduring than those of either cutting or stretching."

Hereditary Chorea of Adults.

A. Huber (*Virchow's Archiv, CVIII*, S. 267) adds, to the few cases of hereditary chorea hitherto known, a series of new observations. He has himself demonstrated the presence of the disease in two sisters, an accurate history of whom he communicates. It seems that the father and aunt of both his patients, and the grandfather and great-grandfather, as well as several other members of the family, have had chorea. Hereditary chorea, he says, presents many variations from the ordinary form, especially in that the chorea is slight, even absent, in voluntary movements. In all Huber's patients, the chorea occurred in the later years of life, and, in the most of them, more or less pronounced psychic disturbances were present. No member of the family that is described by Huber had suffered with chorea of childhood. In the case in which Huber gives the notes of the autopsy, the patient had exhibited during the later years of his life an epileptic insanity, but no longer any chorea. There was found in this case nothing except a pachymeningitis and leptomeningitis of the cervical region.—*Centralblatt f. d. med. Wissenschaften*, July 23, 1888.

Treatment of Rupture of the Bladder.

Dr. A. Blum concludes a communication on ruptures of the bladder and their treatment (*Archives générales de Médecine*, July, 1888) with the following summary: Where the surgeon meets with a rupture of the bladder, or what he supposes to be a rupture of the bladder, he should, without hesitation and as soon as possible, cut down upon the bladder in the linea alba, in order to determine with precision the seat of the lesion and its extent. If the seat of the injury is toward the base—that is to say, if the peritoneum is not involved—perineal cystotomy is indicated. When the rupture is intraperitoneal, the edges of the wound should be brought together with the Lembert suture; the toilet of the peritoneum should be made without drainage. When, by reason of its situation and extent, the wound cannot be brought together, it should be stitched to the abdominal opening, or drainage secured after the manner of Socin, by making an artificial perineal opening. The existence of peritonitis at the outset is not a contra-indication to suture of the bladder. The chances of success, however, are much greater according to the rapidity with which laparotomy has been done.

Treatment in Neurasthenia.

In a paper on neurasthenia, read before the Ontario Medical Association, June, 1888 (*Canadian Practitioner*, July, 1888), Dr. D. Clark, Medical Superintendent of the Asylum for the Insane, Toronto, makes some suggestions as to treatment, of which the following is a summary: Rest and cheerfulness for the anæmic. Outdoor exercise and work for the plethoric and sedative. Fresh air, substantial food, and absolute cleanliness for both classes, as a rule. No chloral, no opium, no alcohol; in short, no artificial stimulant, soporific, or narcotic of any kind. Three hours of natural sleep or rest have in them, he says, more recuperative power than nine hours of stupor or drugged quietude. Such short cuts to rest, he thinks, only murder natural sleep and strangle the heroic efforts of nature to come back to normal conditions. Even when these stilts are used, it must be after serious and thorough deliberation. Any employment which will have a tendency to divert the mind away from self-contemplation and so secure relief by the law of substitution.

He finds that the best remedies are the arsenites, cod-liver oil, phosphide of zinc, pyrophosphate of iron, nux vomica, bromides with caffeine, zinc oxide with ergot, and such like. These tonics and calmatives, he says, assist nature to seek again the old paths. He advises the younger members of the profession, if sedatives or narcotics or stimulants are administered, to mask them as much as possible; for he says he has been told by dozens of victims to the alcohol, chloral, or opium habit, that the first knowledge they had of the pleasurable potency of such drugs was received from the family physician. Dr. Clark's method has been to use some menstruum which will disguise the taste and smell of these drugs and to maintain a stubborn silence as to their presence in his prescriptions.

Society Practice in New Orleans.

The *New Orleans Med. and Surg. Journal*, June, 1888, says in an editorial: "The custom followed by so many physicians in this city, of taking 'society practice,' has grown to such an extent as to threaten destruction to all legitimate work by those few who value the dignity or well-being of the profession. Four-fifths of the people of this city are banded together into so-called 'Benevolent Associations,' whose objects are weekly indemnity while sick, free medical services, including drugs, and free burial in case of death. Every one of these societies annually chooses a physician, a druggist, and an undertaker, and always after fierce competition. Just before the annual election a committee goes around to some fifteen or twenty physicians and the same number of druggists and undertakers, and requests each of these functionaries *to put in a bid.* Then begins the scramble. One physician will offer 'to do the work,' which includes attention to the families of the members, for four dollars per member per annum; another will bid three, another two, and so on until, as actually happened a few weeks ago, the final and successful bidder sees a profit and honor in the job at 'forty cents (40c.) per member per annum, payable quarterly.'"

Summer Drink for School-Children.

Dr. Duchesne, at a recent meeting of the Society of Practical Medicine of Paris, proposed the following formula for a summer drink for school-children. It is a slight modification of a formula of his used last summer with success in French schools. The object of the quassine is to impart a slight bitterness, to quench the thirst better, and to prevent children from drinking more than is healthy for them:

Glycyrrhizin	gr. xvi
Powdered sugar	gr. xvi
Bicarbonate of sodium	gr. xii
Crystallized quassine	gr 1-200
Oil of anise	gtt. ⅔

M. For one powder.

This quantity is to be dissolved in one quart of water when wanted for use. The beverage costs here about half a cent a quart. It would not probably cost much more in America. The idea of giving a slightly bitter taste is not a bad one. Should there be any difficulty in procuring the quassine, either gentian or any of the native bitter principles might be substituted. —*Therapeutic Gazette*, July, 1888.

The Pennsylvania and Maryland Union Medical Association.

The Pennsylvania and Maryland Medical Union Association will this year hold its annual meeting at Birmingham Park on the Brandywine Creek, in Chester County, August 30. It consists of members of the profession, from York, Lancaster, Chester, and adjoining counties, who bring to the meetings their families and friends; the occasion being always one of social enjoyment.

Experimental Feeding of Dogs.

The *Sei-I-Kwai Medical Journal*, of Tokyo, Japan, June, 1888, contains a report on the second experimental feeding of dogs in the Medical School of the Imperial Navy. The object of this experimental feeding of dogs is principally to decide the comparative value of the food given with regard to the power of preserving the health of the dogs, and not to ascertain the relative difficulty or ease of digestion. The experiment lasted fifteen months, and the number of dogs experimented on was six. The general conclusion drawn from the experiment is that barley is superior to rice as an article of food: the dogs fed on rice increased in weight at the beginning, while those fed on barley decreased; but eventually the opposite proved to be the case.

Treatment of Lead Deposits on the Cornea.

In the *St. Louis Med. and Surg. Journal*, July, 1888, Dr. A. D. Williams says that formerly lead deposits on the surface of the cornea were very frequently met with because sugar-of-lead solutions were for many years nearly the only remedy that physicians applied to sore eyes. The result was that, whenever an ulcer of the cornea developed, a deposit of lead took place. Latterly most physicians have learned that solutions of lead are dangerous, and they now rarely use them Sugar of lead is a good and efficient astringent and perfectly harmless so long as there is no break in the epithelium of the cornea. When lead is once deposited on the cornea, it becomes a source of continual irritation, so that an ulcer covered over with lead precipitate can never heal perfectly. On the contrary, the ulcer remains always irritable and often intensely painful, more especially at night. Dr. Williams says that he recently saw a colored man who had a large corneal ulcer plastered over with lead deposit. He had not been able to sleep comfortably for many years. The eye was not much reddened, but intensely irritable. It will be understood that in such cases the lead deposit is the indirect cause of the suffering. It prevents the re-formation of the epithelium, and consequently the nerves are constantly exposed to the atmosphere, and the injury is painful for the same reason that a fresh burn is painful.

The treatment, Dr. Williams says, is simple and easy. The lead deposit must be scraped off completely so that the ulcer can heal and exclude the air from the nerve-terminals. The scraping must be thorough, so as to remove every particle of lead. Formerly chloroform had to be given in these cases. Now cocaine is all-sufficient to prevent pain. The scraping is done with an ordinary knife, holding the edge vertical to the cornea and scraping back and forth till the white lead deposits are all removed. A solution of atropine should be used for a few days till the ulcer has healed over. The result is very gratifying to the patient, because it gives prompt relief from his suffering.

Colotomy.

In a paper on colotomy read before the Missouri State Medical Association, April, 1888, Dr. N. B. Carson gives his preference for Littre's operation (opening the bowel in the groin) for the following reasons (*St. Louis Courier of Medicine*, July, 1888):

"1. It is, when carefully done, not more dangerous than the lumbar operation.

"2. We are enabled to determine the exact seat of the disease, and, as a result, fix the intestine at any desired distance from the seat of the disease.

"3. The patient is by far more comfortable, from the fact that he is enabled to attend to himself without the aid of others.

"4. We are better able, with the opening in the groin, to fit a pad or truss which controls more perfectly the discharges, and with less discomfort, than when the lumbar opening is selected.

"5. That, in this operation, we are enabled to make a knuckle in the bowel, to prevent a passage downward of the feces, without adopting Madelung's method of dividing the bowel across and closing and dropping the lower end.

"6. When desirable, the artificial anus may be more readily closed in the inguinal than in the lumbar region."

Liquid Glue.

The *Chemist and Druggist* quotes the following formula for a glue, which is specially serviceable for wood and iron, from *Rundschau*, and says it possesses great resisting power:

Gelatine	parts,	100
Glue	"	100
Alcohol	"	25
Alum	"	2
Acetic acid (20 per cent.)	"	200 (or q. s.)

Heat the whole together for six hours.

Naphthaline in Dysentery.

Hinterhof (*Russkaya Meditzina*) praises the good effects of naphthaline in dysentery. His formula is:

Pure naphthaline	gr. xv
Distilled water	f℥ii

To be used in two enemas.

Besides the naphthaline, he administers quinine. Tenesmus and smarting at the anus subside at the first enema, and recovery is established after the second.—*Bulletin Médical*, July 8, 1888.

Foreign Bodies in the Male Urethra.

Dr. B. C. Atterbury, in a communication in the *China Med. Missionary Journal*, March, 1888, says: "It seems that among some of the Taoist sects there are those who, for the purpose of warding off disease and fortifying the system, pay great attention to medical gymnastics, or what is known in China as *kung fa*. One of their practices is to introduce into the urethra bougies with the idea of keeping open the 'path of life,' preventing stricture, and curing spermatorrhœa. Dr. Dudgeon, in his hospital report for 1873, gives an interesting account of one of these cases. His patient was a Manchu, about 30 years old, who had joined one of these sects. For ten years he had inserted every night into his urethra a lean bougie, removing it in the morning. These bougies are of various sizes. When about to be introduced, they are rubbed with mercury, and are carried by their own weight toward the perineal region, where they can be felt. In the morning their extraction is effected by turning the body to one side and using a little pressure. Seven days before the operation he had made a sudden jerk on rising in the morning, and the little bougie reversed its usual practice and dropped into the bladder, where it was found. It weighed 256 grains and measured two and a half English inches. Dr. Bushell also tells me of an analogous case, in which he removed from the membranous portion of the patient's urethra a piece of pewter two inches long and shaped like a bougie. At the time, he was told that the man was a member of a Taoist sect." Dr. Atterbury then states that he has recently seen two similar cases, which were operated upon within a week of each other—one at the An Ting Mên hospital, and the second at that of the London Mission. The bougies in both these cases were pieces of bone chop-sticks, about 2½ inches long, and carefully rounded at both ends. Dr. Atterbury's patient would say but little as to how the piece of bone got into his bladder, but, from his account, the nine months during which he affirms it was there must have been a time of great suffering. It was easily removed by the median operation. An incrustation of the phosphates had formed around the article, which weighed altogether 465 grains.

But little information can be gotten from the Chinese beyond what is here given on this subject, since little is known about it outside of the members of the sect, and they are said to be sworn to secrecy. These cases, however, show that the practice of inserting these bougies cannot be a very uncommon one, at least in Peking. In some cases, it is said to be a punishment inflicted by the injured husband upon a man taken in adultery.

Etiology of Biliary Lithiasis.

In a communication in the *Wiener med. Wochenschrift*, No. 23, 1888, Dr. Zerner reports the following case as an example of the influence which compression of the liver can exert upon the formation of biliary calculi: An officer died in the hospital after a right-sided pleural effusion had been diagnosticated. At the autopsy, a hemorrhagic pleural effusion was found, and besides that a focus of encysted pus situated between the diaphragm and the convexity of the liver. The right lobe of the liver was compressed and depressed by this abscess, and contained a large number of biliary calculi. The author is of opinion that there must be more than an obstacle to the flow of the bile in order that calculi should be formed—that there must be also a pathological alteration of the wall of the excretory vessels, which obstructs the resorption of the solid elements in a greater measure than the resorption of the watery parts. He does not accept, therefore, the theory of Marchand, that biliary lithiasis is due to pressure by the corset. He thinks the chief cause of biliary lithiasis is to be found in a sedentary habit. This entails, as a consequence, an increase of intra-abdominal pressure, which in turn restricts the movements of the diaphragm, and then the flow of bile into the intestine; moreover, the sedentary habit predisposes to gastro-intestinal affections. Finally, Beneke has proved that seventy per cent. of persons with biliary lithiasis have arterio-sclerosis. It is very probable, he says, that the walls of the bile-ducts participate in the alteration of the walls of the blood-vessels.—*Gazette Médicale de Paris*, June 30, 1888.

Multiple Paralysis of Cerebral Nerves.

H. Unverricht (*Fortschritte der Medicin*, No. 24, 1887) communicates the history of a man thirty-eight years old, who had had a sore when twenty years old, but in other respects had had no decided symptoms of syphilis. This man noticed suddenly, while at work, that he could not hold his pipe in his mouth, and immediately showed bilateral facial palsy. The latter was followed by a unilateral paralysis of the soft palate, paralysis of the right oculomotor, of both abducentes, and by disturbances in the parts supplied by sensory fibres of the trigeminal of both sides, accompanied with neuroparalytic inflammation of the right cornea. After his admission to the hospital, he developed, within fourteen days, a paralysis of nearly all the cerebral nerves, only the left optic and the left trochlear nerves being demonstrably unaffected. Toward the end of his life, paralysis of the muscles of the extremities, as well as of the trunk and neck, occurred. The sensibility in the upper extremities was blunted. After eight weeks' illness, the patient died of gangrene of the lung, as the result of food passing into the windpipe. At the autopsy, there was first found a round-celled sarcoma in the mediastinum, of the size of an apple; metastatic growths from this were then found between the dura and base of the skull, which more or less blocked the openings in the latter and compressed the individual nerves.—*Centralblatt f. d. med. Wissenschaften*, June 23, 1888.

"Officinal" or "Magistral."

The Paris correspondent of the *Therapeutic Gazette*, July, 1888, says: A question of French has been decided by the Academy of Medicine of Paris. A short time since, the French premier requested the Academy to define exactly the pharmaceutical terms "*officinal* and *magistral*," the distinction being of some importance, for administrative reasons unnecessary to mention. The Academy appointed on the question a committee composed of MM. Planchon, Lefort, Bourgoin, Dujardin-Beaumetz, and Prunier, all shining pharmaceutical lights, and last Tuesday the committee presented a unanimous report, which will, of course, be adopted by the Academy, and, consequently, by the administration. As the definition settles a question hitherto very puzzling to foreign readers of French therapeutical and pharmaceutical literature, it is interesting to here relate it. According to the academical committee, "*officinal* medicaments are those whose formulas and mode of preparation are given by the Codex, and which, besides, will keep a long time without noticeable alteration. The *magistral* are such medicines as the pharmacist prepares when prescribed, and dispenses immediately, without regard to their keeping-properties." Such, it may be remarked, is the usually accepted meaning of the terms in general. But, to be more precise, the committee added: "1. Such medicaments only should be considered *officinal* which keep easily, and whose formula and mode of preparation are mentioned in the Codex, if they are galenical, or whose characters and method of purification and testing are given, if chemical. 2. It does not follow, nevertheless, that all medicaments mentioned in the Codex are necessarily officinal. Potions, tisanes, juleps, etc., are by nature essentially magistral, like all mixtures prescribed by the physician, even when exclusively composed of officinal medicaments. The fact alone of the mixing causes them to become magistral remedies." It is scarcely necessary to point out the different meaning of the word *officinal* in the two languages. In English it is applied to pharmacopœial drugs and medicines. In French it is derived from the word "*officine*," drug-store, and just means store medicines—that is, kept in stock.

Southern Surgical and Gynecological Association.

At the next meeting of this Association, to be held at Birmingham, Alabama, September 11, 12, 13, 1888, the following papers will be read: The President's Annual Address, W. D. Haggard, M.D., Nashville, Tenn.; the Annual Oration, W. F. Hyer, M.D., Holly Springs, Miss.; Floating Kidney, with Vicarious Menstruation, DeSaussure Ford, M.D., Augusta, Ga.; Gastrostomy, W. B. Rogers, M.D., Memphis, Tenn.; The Medical Treatment of Fibroid Tumors of the Uterus, Bedford Brown, M.D., Alexandria, Va.; Indications for Operative Interference in Cerebral Troubles, T. O. Summers, M.D., Jacksonville, Fla.; A Case of Tubal Pregnancy, Presenting Interesting Medico-Legal Relations, E. P. Sale, M.D., Aberdeen, Miss.; Superinvolution of the Uterus following Trachelorrhaphy, Virgil O. Hardon, M.D., Atlanta, Ga.; I, Dermoid Cysts of the Coccygeal Region, and II, Electrolysis in Gynecology and Surgery, E. J. Beall, M.D., Fort Worth, Texas; Alexander's Operation,

W. L. Nichol, M.D., Nashville, Tenn.; Hysterectomy in Cancer of the Uterus, W. H. Wathen, M.D., Louisville, Ky.; The Extravagancies and Impracticable Requirements of Modern Antiseptic Surgery, so far as the Country Practitioner is Concerned, J. M. Taylor, M.D., Corinth, Miss.; Treatment of Fractures with Plaster-of-Paris Splints, W. F. Westmoreland, Jr., M.D., Atlanta, Ga.; The Present Status of Electro-Therapeutics in Gynecology, J. R. Buist, M.D., Nashville, Tenn.; Antiseptics in Surgery and Gynecology, F. T. Meriwether, M.D., Asheville, N. C.; The Attitude of Removal of the Uterine Appendages for the Cure of the Convulsive Neuroses, W. Locke Chew, M.D., Birmingham, Ala.; Interesting Cases of Surgery, R. M. Cunningham, M.D., Pratt Mines, Ala.; My Antiseptic Bags, or Practical Aseptic Surgery, J. W. Long, M.D., Randleman, N. C.; The New Departure in Uterine Therapeutics—The Dry Method, T. A. Means, M.D., Montgomery, Ala.; A Study of the Various Methods of Treatment of Laceration of the Perineum, and Rectocele, with Report of Cases, J. H. Blanks, M.D., Meridian, Miss.; Report of a Case of Spinal Concussion, Jno. R. Page, M.D., Birmingham, Ala.; Fractures of the Forearm, Jno. Brownrigg, M.D., Columbus, Miss.; Some Practical Thoughts in Surgery, James Guild, M.D., Tuscaloosa, Ala.; Perineal Lacerations, M. C. Baldridge, M.D., Huntsville, Ala.; Electrolysis in the Treatment of Urethral Strictures, S. M. Hogan, M.D., Union Springs, Ala.; The Field and Limitation of Laparotomy, I. S. Stone, M.D., Lincoln, Va.; Operative Procedures in Hypertrophy of the Prostate, R. D. Webb, M.D., Birmingham, Ala.

The Association will convene in the hall of the Y. M. C. A., at 10 o'clock A.M. each day. The Annual Oration will be delivered at O'Brien's Opera-House on the evening of the first day's session, at which time the Mendelssohn Club of Birmingham will give a concert for the entertainment of the Association. Entertainments have been arranged by the local committee to take up all the hours not occupied by the sessions. Hotels and railroads will give reduced rates; but only those holding certificates, signed by the ticket-agent at the point where through ticket to the place of meeting was purchased, will be entitled to the two-thirds reduction in return fare.

W. D. Haggard, M.D.,
President.

Wm. E. B. Davis, M.D.,
Secretary.

NEWS.

—Dr. Raphael, of New York City, died at Saratoga, August 4, after a short illness.

—Dr. R. L. Boyle, of Raymond, Miss., died July 13, 1888, after an illness of three weeks.

—Twelve new cases of yellow fever and two deaths were reported at Jacksonville, Florida, August 11.

—Two cases of trichinosis have been recently reported to the New York Board of Health, by Dr. Seibert.

—Dr. J. P. Campbell, a special student at Johns Hopkins University, has been appointed Professor of Biology in the Georgia State University.

—The Texas Medical College and Hospital, at Galveston, which was discontinued in 1887, has been revived. Lectures will be given, beginning October 15, 1888.

—Dr. Sahli has been appointed Professor and Director of the Medical Clinic at the University of Berne, succeeding Professor Lichtheim, who has gone to Königsberg.

—The *Atlanta Med. and Surg. Journal*, August, 1888, states that a movement has been started in that city looking to the establishment of a hospital for the indigent sick.

—The *New Orleans Med. and Surg. Journal*, August, 1888, states that diphtheria is again on the increase in that city. During last June, there were 50 cases and 22 deaths.

—Professor Hertwig will give instruction in embryology, hereafter, at the University of Berlin, and Professor Waldeyer will confine himself to general and microscopical anatomy.

—Professors Fritsch, of Breslau, and Kaltenbach, of Halle, having both declined the Chair of Obstetrics at Würzburg (Scanzoni's chair), it has been offered to Hofmeier, of Göttingen.

—Dr. Frank A. Tompkins, of Sandy Point, Texas, was recently shot in the back by a man named Day, with whom he had had some dispute. There is believed to be a chance of his recovery.

—The small-pox hospital at Aubervilliers, France, has been charged by M. Créquy with having been the cause of an outbreak of small-pox among its attendants. He recommended that such hospitals should be removed at least 500 or 1000 yards from any dwelling, and that all attendants should be revaccinated.

—The brig "Teneriffe," which was detained in quarantine at the Delaware Breakwater, was discharged August 7. The captain and seaman who had yellow fever have recovered and have returned to the vessel.

—The latest reports from Florida indicate that yellow fever is spreading from Plant City and Manatee to other places. Cases are now reported from Sandford and Jacksonville. There is some fear expressed lest an epidemic may occur in the latter city.

—The *Lancet*, July 28, 1888, says that a kind of epidemic of hysteria has developed at Pavia. About twenty women and girls were found in a small room, lying on straw, and affected from time to time with hysterical convulsions, followed by excitement, laughing, gnashing of the teeth, and other hysterical symptoms.

—Chattanooga, Tenn., has established quarantine against Jacksonville and all yellow fever infected points. A carload of Jacksonville refugees who were *en route* to Chattanooga were met at the depot on Saturday by the Mayor and Board of Health, and not permitted to remain over. They are said to have gone North.

—Surgeon-General Hamilton and officials of Savannah and Charleston, at a conference at Way Cross, Ga., August 12, decided that it is necessary speedily to deplete the city of Jacksonville, and to that end a camp of refuge, in charge of Dr. Guitéras, will be located at Boulogne, on the Savannah, Florida and Western Railroad. The Government will send tents there at once. The sick will not be allowed there, but will be sent back to Jacksonville for treatment.

—Dr. H. F. Formad, in a very interesting article in the *Journal of Comparative Medicine and Surgery*, July, 1888, takes the ground that "it can be regarded as established that the microscopist has ample and sure means to diagnose fresh or well-preserved human blood from that of certain animals, provided he has the proper experience and employs rightful and honest means." He relies largely, as intimated, upon the microscope for this differentiation, using a 1-18 Zeiss homogeneous immersion lens, which magnifies about 2250 diameters. Microphotographs made from this amplification, magnified to the uniform scale of 10,000 diameters, show recognizable differences in size between the blood corpuscles of man and those of the domestic animals, dog, ox, sheep, and goat, whose corpuscles nearest approach in size those of man.

HUMOR.

Repeated visits of Sir William Jenner to Windsor Castle, recently, gave rise to the story that the Queen was suffering from insomnia, but this is emphatically denied. The Doctor was merely making the sort of visits he Jennerally pays when the Queen is at the Castle.

Gentleman: "What's the matter, Uncle Rastus? You look sick." Uncle Rastus: "Yes, sah; I ate er whole watermelyun larst night, jess 'fore I went ter bed, an' I ain't feelin' bery well dis mawnin." Gentleman: "Are you going to see a doctor?" Uncle Rastus: "No, sah; I'se gwine fo' anudder melyun."—*New York Sun.*

Mr. Crowley, the Central Park chimpanzee, is sick, the result of a watermelon gorge he indulged in a few days ago, and the New York papers are describing the treatment his family physician is giving, together with bulletins about his (Crowley's) condition. Monkeying with a watermelon may not be good for Mr. Crowley's comfort, but it has wrought his importance up to an altitudinous point.—*Phila. Ledger.*

A Weather Expert. — Passenger (to stranger): "So you think we are to have a hot summer, sir." Stranger (pounding the seat): "Think? I don't think anything about it—I *know* so! The whole country, sir, will sizzle until snow flies!" Passenger: "You seem to be positive." Stranger: "Positive? Why, I am as sure of it as I am that I run the finest hotel in the Dogskill Mountains! Put that card in your pocket; it may save your life."—*Life.*

The *Boston Med. and Surg. Journal*, July 19, 1888, says that "the alarming complications which may attend even the mitigated form of the duello which prevails in France is illustrated by the following paragraph, which was thought worthy of being telegraphed under the Atlantic to a morning paper: 'There seems no reasonable doubt of Boulanger's recovery within a fortnight or so, although his wound appears to threaten him with all sorts of unpleasant complications, such as lockjaw or the less familiar complaint of embolic, caused by clots of blood in the bronchial tubes, or, what is still rarer, suffocation by hæmaturia in the respiratory channels.'"

MARRIAGE.

Comstock—Cullinan.—July 18, 1888, Dr. A. J. Comstock, Jr. (Jeff. Med. Col., 1884), to Miss Elizabeth W. Cullinan, both of San Buenaventura, California.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled **Norwegian Oil,** rendering it by common consent the **Best Emulsion in the market.**

Clinical Lecture.

ON ISOLATION IN THE TREATMENT OF HYSTERIA.[1]

(A Lecture delivered in the Salpêtrière Hospital.)

BY PROFESSOR J. M. CHARCOT,
PARIS, FRANCE.

Gentlemen: Before returning to the principal subject of our present studies, I thought it would be of use to tell you something about those three children belonging to one family, whom I brought before you on the 19th of last December. I have no intention of repeating the history of this little epidemic of hysteria, developed under the influence of the practices of spiritualism: all the details I have given you in my previous lecture. I shall call to your mind only certain particulars needful to refresh your memory as to the condition of these children at the time they were presented to the clinic, in order that you may be enabled to-day the better to judge of the modifications which have been effected in them under the influence of the measures we have adopted and of the treatment which we have instituted.

The family, I may remind you, consists of three children—two boys and a girl. It is with the latter, aged 13½ years, that the affection began August 28, 1884, as the sequel of a séance of spiritualism which was prolonged from 9 o'clock in the morning till 7 P.M., and in which Julie played the rôle of medium. At the end of the séance, she was taken with convulsive paroxysms, which were repeated from fifteen to twenty times a day, till the admission of the whole family to the Salpêtrière, December 9, 1884. You remember that the two brothers had followed the deplorable example set by their sister, and November 15 the younger of the two, François, aged 11 years, about six weeks after the famous séance of spiritualism (which, by the way, had made no impression on him), was taken with a fit of hysterical delirium while still confined to his bed by an attack of rheumatism. Two days later, November 17, Jacques, the older of the boys, in his turn, had fits of delirium with hallucinations.

From this time forth, the three children could never come together in the house without having fits. The girl would begin, her brothers would follow her example, and this would happen several times a day; this unfortunate state of things, of course, could not be allowed to continue. Then it was that the parents besought us to interfere, and that we proposed to take their children into our service, to which they consented.

I. The proposition which I made to the parents, itself, contained a series of therapeutic considerations which I must now set forth. Admission to the hospital enabled me to effect:

The removal of the patients from the place where their disease first declared itself;

The absence of the father and mother, who had themselves become very nervous, and whose presence would, necessarily, according to my long and invariable experience on this point, prevent any effective treatment;

The respective separation of the three children.

The girl, in fact, was placed in one of the female wards of our clinical department. The two boys were put in the only male

[1] Continued from Reporter, page 68.

ward which we possessed at that time. The respective isolation of the three patients was not, then, altogether complete; we had, however, done the best we could to keep them apart. Such, in my mind, should be the fundamental conditions of treatment: the parents consented no longer to see the children but with my permission, and I seemed, myself, warranted in assuring them that, in all probability, in a few months we should be able to send home their children completely restored to health.

Such was the moral or psychical side of the treatment proposed; we reckoned, of course, on carrying out at the same time the medical treatment, properly so-called. The children confided to our care were, all three, pale and anæmic, and needed reconstituents, among which bitters and ferruginous tonics hold the first place. There was an indication, also, to endeavor to modify the rheumatic diathesis, which was so well marked, at least in one of them.

As for those agents which are addressed particularly to the hysterical state, we counted much on putting in practice the treatment by static electrization which renders us every day, in these cases, so great service, and this especially in default of a methodical hydrotherapic treatment, our hydrotherapic establishment of the Salpêtrière not being yet in good working order. We did not found any expectation on the employment of the bromides, experience having long taught us that this class of medicaments, which almost always acts well (at least to a certain extent) in epilepsy, remains completely inefficacious, not only in ordinary hysteria, but also in that form of hysteria which seems most to resemble epilepsy, namely, hysteria with epileptic form, or hystero-epilepsy. I say nothing of opium in large doses, or of other anti-spasmodics, the employment of which I do not condemn altogether, but which seem to me totally to have failed in such cases.

II. But I must confess, gentlemen, that if I had a mind to put in practice all the therapeutic agents, so-called, I should rely mostly on isolation, that is to say, on moral treatment, although, in the particular instance of these children, it was necessarily incomplete. In fact, it was possible for all three of the children to meet in this hospital even—a thing which has often happened; moreover, the two brothers occupied the same ward, and, like their sister, could have before their eyes, and on different occasions, in the common sleeping-rooms, various manifestations of convulsive hysteria. But we could not help this, and, in my judgment, it was better for them to live in these conditions than to remain under the paternal roof, in perpetual contact with the father and mother, and in close relations with them all the time.

I cannot too much insist upon the capital importance which I attach to isolation in the treatment of hysteria, where, indisputably, the psychical element in the majority of cases plays a considerable, if not a predominant, part. It is now nearly fifteen years that I have firmly held to the necessity of isolation in this disease, and all that I have seen during this time only tends to confirm me more and more in my opinion. Yes, it is necessary to separate growing and adult children from their father and mother whose influence, as experience shows, is especially pernicious. Experience, I repeat, proves this absolutely, although it may not always be easy to assign a reason for this, especially to mothers, who are apt to give a deaf ear to such considerations, and generally yield only at the last extremity.

In city practice, isolation, such as I have urged, is, in fact, of everyday occurrence in cases of this kind, and the conditions for such isolation in a city like ours are ample and excellent. In Paris, for the last fifteen years, hydrotherapic health-institutes (*maisons de santé*) treat such patients with complete success, possessing admirable arrangements for this end. In the provinces, isolation is more difficult to effect, for establishments suitably furnished and managed are generally wanting: it is quite possible to organize private health-resorts on a small scale, but you readily understand that they would necessarily be poorly equipped for doing thorough and systematic work.

In the hydrotherapic *maisons de santé*, the patients are placed under the direction of competent and experienced nurses who are generally Sisters of Charity, who have become, by long practice, very expert in the management of this kind of patients. A kind but firm control, much calmness and patience, are here indispensable conditions. The parents are systematically kept away till the day when, by reason of a notable improvement in the condition of their children, the latter are permitted, *as a recompense*, to see them; first, at long intervals, then oftener, as recovery becomes more pronounced. Time and hydrotherapy, to say nothing of the internal treatment, accomplish the rest. For my part, I have the firm conviction that incipient hysteria,

especially in young subjects and particularly in males, may often be nipped in the bud, if it is possible to persuade the parents to take energetic measures from the very start, and not to wait till the disease takes root and develops in consequence of having been too long left to itself.

III. In order to make plain this remarkable influence of isolation in the treatment of hysteria in young subjects (in this category marriageable girls being included), I might cite numerous instances in which it has proved to be singularly efficacious. But, not being able to enter into long details, I will give you the particulars of one case which seems to me to be a typical one, and very appropriate to my purpose.

My narration concerns a young girl of Angoulême, thirteen or fourteen years of age, who, for five or six months, had grown very rapidly, and who, all at once, utterly refused all nourishment, although there was no trouble with deglutition, or any disorder on the part of the stomach. It was one of those cases that border on hysteria, but which do not always properly belong to it, but which have been described by Lasègue in France, and by Sir William Gull in England, under the name of *nervous anorexia*, or *hysterical anorexia*. The patients do not eat, they are not willing or able to take food, although there is no mechanical obstacle to the passage of the food or to its sojourn in the stomach when once ingested. Sometimes they eat on the sly, but not always, as has been supposed; and, although the parents themselves favor this deceit by placing articles of food in places where they may easily find them and devour them unobserved, yet alimentation remains always insufficient. The family waits weeks, months, always hoping that the desire for food will return. The repugnance of these patients for eating cannot be overcome by entreaties, supplications, or violence. Then emaciation ensues, and may attain extravagant proportions: it is no exaggeration to say that these patients become living skeletons. And what a life! Cerebral torpor succeeds the unnatural agitation of the first period; for a long time, walking and standing have become impossible; the patients are confined to their beds, where they can scarcely move; the muscles of the neck are paralyzed, the head rolls as an inert mass on the pillow; the extremities are cold and cyanosed, and the wonder is expressed how life can continue in such a physical wreck.

The parents have long been alarmed, but this alarm has reached its climax when affairs have come to this point; nor are such fears without good foundation, for a fatal termination threatens, and I know at least four instances in which death ended the scene.

Such was almost the situation of the little patient of Angoulême, when I received a letter from her father, setting forth the lamentable condition of his child and entreating me to come and see her. Such a journey on my part, I replied, was unnecessary; I could, without seeing the patient, give the proper advice. "Bring the child to Paris," I said, "place her in one of our hydrotherapic establishments, leave her there, or at least impress it upon her mind that you have quit the capital, then let me know, and I will take charge of the rest." To this letter, no reply was made.

Six weeks later, one morning a practicing physician of Angoulême came to my office in an anxious state of mind, and told me that the little patient, whom he had been treating, was in Paris, in one of the establishments that I had designated; that she had been going on from bad to worse, and in all probability had but a few days to live. I asked why I had not been informed of the arrival of the young girl. He replied that the parents had refrained from notifying me because they had resolved not to be separated from their child. To this I responded that the principal element, the condition *sine quâ non* of my directions, had been neglected, and I declined any further responsibility in this unhappy case. Nevertheless, yielding to his entreaties, I went to the hydrotherapic establishment in question, and there I saw a lamentable spectacle: that of a grown-up girl, fourteen years of age, who had reached the last stage of emaciation and marasmus, prostrate in bed, extremities cold and purplish, voice extinct, head drooping, and presenting, in all the leading features, the picture which I have just given you. There was really occasion for being anxious, very anxious.

I took the parents one side, and, after severely remonstrating with them, I told them that there remained, in my opinion, only one chance of success, namely, that they should go away, or seem to go away, immediately, and leave their child to the care of strangers. They might say that they were obliged, for some cause, to depart immediately for Angoulême, and put upon me the responsibility for this procedure. At all events, the child must be made to believe that they had taken their departure, and the sooner the better. Their consent was difficult to obtain, notwithstanding all

my remonstrances. The father, in particular, could not understand why a physician should insist that a parent should separate himself from his child in time of danger; but I was firm in my conviction, and urged it upon them with all my powers of persuasion; the mother yielded first, and the father finally consented under protest, having little faith in the success of this experiment.

The isolation was effected; its results were rapid and marvelous. The child, remaining alone with the Sister of Charity who had care of her, and the resident physician, cried for an hour or two, but mourned much less on account of the separation than one would have expected. That very evening, in spite of her repugnance, she consented to take half of a little biscuit soaked in wine. The days following, she took a little milk, wine, broth, and a small quantity of meat. Alimentation was established, and went on progressively but slowly.

At the end of a fortnight, there was considerable improvement in her condition. She was taking a fair amount of food; her strength returned with plumpness, and, at the end of a month, I saw the young girl sitting in an arm-chair and capable of holding her head erect. She could walk a little; then hydrotherapy was resorted to, and, after two months, dating from the outset of the treatment, she might have been considered as almost well; as far as strength, appetite, and flesh were concerned, there was little left to desire.

Then it was that the young patient, on being questioned by me, made this confession: "Till papa and mamma had left me, and till I saw that you were master (for I well knew that you wanted to make a prisoner of me), I could not be convinced that my case was serious, and, as I had a horror of eating, I refused to eat. *When I saw that you were master*, I was afraid, and, in spite of my repugnance, I endeavored to eat, and my appetite by degrees came back." I thanked her for confiding to me this statement, which is itself a lesson.

IV. I might easily multiply instances illustrative of the favorable influence of isolation, judiciously carried out, in the treatment of certain nervous diseases which do not, strictly speaking, belong to the category of mental alienation, and of hysteria, or even of neurasthenia in particular. What I have just said, in fact, respecting hysterical anorexia, I may also say respecting most forms of the hysterical neurosis. But it suffices me, for the present, to have called your attention to the curative influence of isolation; it is a subject to which I shall have occasion many times to return, without doubt, in this course of lectures, being one on which I have spoken every year for fifteen years, and many of the lectures which I have devoted to it have been published. This method has, moreover, won general acceptance, for I see that in Germany, in particular, as well as in England and America, its efficacy has begun to be authoritatively proclaimed. Therefore, I make bold to claim for ourselves and our institution the priority in this matter, for, if I mistake not, the method legitimately belongs to us, at least as far as the treatment of hysteria and allied affections is concerned. Isolation, in fact, is the capital element in the method of treating neurasthenia and certain forms of hysteria, advocated the last few years by Weir Mitchell in the United States, Playfair in England, and Burkhart in Germany.[1]

V. But I see that it is time to return to our young patients. You will be interested in knowing how they have been faring the last six weeks, since we instituted the treatment in which, in my judgment, isolation has played the principal part. In a general way, amelioration has been observed simultaneously in all three, beginning with the boys, as I have before told you.

The youngest, François, may be considered as well. He has had no convulsive attack for a fortnight, and to-day he has gone home to spend the holiday with his father; I understand that he has stood this test well and triumphantly. I have not quite as good news to tell you of Jacques, the older brother, who, moreover, was the last taken. The *grand crises* have completely left him; nevertheless, they have been replaced by slight attacks of vertigo, quite like those of epileptic vertigo, which, however, have become very infrequent the past fortnight. He did, however, at his father's house, where he accompanied his

[1] R. Burkhart.—Zur Behandlung schwerer Formen von Hysterie und Neurasthenie. (Volkmann's Sammlung, 8 Oct., 1884.)

[In a foot-note, Charcot shows that, while to the school of Salpêtrière belongs the credit, in these modern times, of most effectively systematizing isolation in the treatment of hysteria, yet such treatment is really of ancient date, the necessity of which was recognized by physicians hundreds of years ago. He cites Jean Wier (1564), who, in a book entitled *Histories, Disputes, and Discourses on Illusions and Impostures of Devils*, urges the necessity of removing these "possessed" girls (hysterics) from their parents and friends to suitable religious asylums, where suitable moral instruction and discipline might be imparted, and where they might be dispossessed of the demoniacal influence.]

younger brother one day, have one of those slight vertiginous crises which I am in the habit of designating *petit mal hysterique*.

The young girl did not accompany her brothers home, but has remained at the Salpêtrière, for we were far less sure of her than of her brothers. She is, moreover, not yet cured, although from day to day her crises diminish in intensity, in length, and in frequency. She would certainly have got along a great deal faster if, in the ward which she occupies, she had not been in constant communication with patients afflicted with hysteria major, attacks of which she sees every day. But we have not been able to do better by her, not having any separate ward at our disposal. However, her condition has much improved; for, what is pretty decisive evidence, the children have all three of them been several times together in the electrotherapic room without any attack supervening.

I am going to present to you first the boys, then the girl, for, as I have said, I am not so confident of her, and I fear lest the sight of this assembly may disturb her to such a degree as to provoke some sort of hysterical attack. I will also show you, in connection with all three, that the hysterical stigmata have undergone modification, as well as the spasmodic or delirious crises; this is an important fact, for I do not think that we can consider an hysterical patient as cured while the stigmata still persist. Here is little François, aged eleven years; he has advanced the farthest toward recovery. You observe that he has a better appearance than formerly; the tonic treatment and the hospital fare (which is, however, not yet what it should be) have improved his general health. As for the stigmata, I will recall to your mind that these consisted, in his case, in a general anæsthesia limited to the face, and especially to the forehead. He did not perceive odors, and his pituitary membrane was not influenced any more by perfumes than by ammonia or acetic acid; hearing was obtunded, and we could introduce little horns of paper into the external auditory meatus without the sensibility being affected thereby. The general sensibility of the tongue, as well as the taste, was completely abolished; we could put aloes or sulphate of quinine on the tongue without eliciting the least perception of its presence.

In this connection, I may mention that a fortnight ago I showed this little patient to my eminent confrère of London, Dr. J. Russell Reynolds, who was making a brief stay in Paris, intending to call his attention to these troubles of gustation. I own that I was agreeably surprised to see our little man draw back his tongue with a hideous grimace; this indicated to me that our method of treatment had borne its fruits, and that the patient was on the road to recovery. His condition, moreover, has not ceased to improve, as far as the taste is concerned, as you yourselves can judge.

Vision, as you know, presented also quite special disturbances, which, if it is true that they do not properly belong to hysteria, are met so frequently in this affection that we can ascribe to them a great diagnostic importance. The contraction of the visual field was very pronounced on both sides, but, while on the right there was no transposition of colors, on the left side not only was the circle of red outside of the circle of blue, but it also passed beyond that of the white light. A new campimetric examination, made ten days ago by M. Parinaud, showed us that all these troubles had vanished, and that vision had become normal.

I have already told you that the crises had completely disappeared; let me remind you how numerous they were, for they averaged three a day for a long time, giving a total of twenty to twenty-five attacks per week.

I now present to you little Jacques, oldest of the boys, twelve years of age, who was taken last, though less seriously than his brother, and did not have any permanent hysterical stigmata. In him the minor form (*petit-mal-hysterique*) greatly predominated over the major (*grand-mal-hysterique*); nevertheless, there was one time when he was having fifteen fits a week. For the last fortnight, he has had but two attacks of vertigo; one of these happened yesterday under circumstances which I have mentioned. In this connection, I may say, once for all, that cases of this kind are an imitation of epileptic vertigo, or petit mal, nothing more. The epilepsy is only in the form, not in the substance; and, in reality, *petit-mal-epileptic* and *petit-mal-hysterique* are two things radically different.[1] You will remark, furthermore, that, if the general condition of this child has improved, he is still, in many respects, far from being well.

Here is little Julie, the oldest of the three It seems to me that she has grown taller and stouter within a month; at any rate, her condition is much more satisfactory. As to

[1] See, in this connection, 1, Bourneville and Regnard, Iconogr. photogr. de la Salpêtrière, t. i, p. 49, and t. ii, p. 202. Bourneville, *Clinical and Therapeutical Researches on Hysteria*, etc. (Compte rendu du service des enfants de Bicêtre pour 1883, p. 100.)

her hysteria, you remember that she was having on an average, every day, four or five attacks or series of attacks which lasted from half an hour to an hour and a half. For the last fortnight, she has not had these fits oftener than twice or three times a week; they are less violent, and hardly last a quarter of an hour. You know that she had certain well-characterized hysterogenous points, situated on both breasts, the external part of both flanks, the calves, the two external malleoli, and the internal part of the right elbow-joint. The zones on the two breasts, the calves, and the right elbow have disappeared; there is no longer ovarian sensitiveness (*ovarie*), but there are a few patches of anæsthesia irregularly distributed on the left side. The hysterical amblyopia, which in her case was very pronounced, has not now existed for ten days; lastly, as I have told you, she can with safety meet her brothers, no attack being provoked thereby.

Such is the situation, and there is every reason to expect that we shall soon see the end of this little family drama, or, if you please, *comedy*, for there is nothing of a very serious or gloomy character in all these events. In about ten days, we shall send the oldest boy home; the youngest goes to-day, and the girl will leave us a little later.[1]

I present for your meditation the lesson which the story of these children brings with it. I believe that by means of the measures which I have set forth we may sometimes succeed in nipping in the bud, especially in males, nascent hysteria, hysteria of childhood. I am now speaking of this latter only, for, when this neurosis has become inveterate in adults, the chances of success, though still great, are much more doubtful. As far as these children are concerned, I believe that, despite the nervous predisposition which seems so pronounced in all of them, they will henceforth, for a long time, if not forever, be free from hysterical manifestations. The parents, taught by sad experience, will certainly henceforth keep them from the practices of spiritualism. Knowing the weak points in their children, they will endeavor, I hope, by the help of a hygienic discipline, which shall comprehend as well physical as intellectual and moral culture, to avert any further occurrence of like untoward incidents.

[1] The youngest of the boys is to-day completely cured; for more than a fortnight, the girl has had only one slight attack during a visit of her parents at the Salpêtrière.

COMMUNICATIONS.

SEA-SICKNESS.

BY JOHN M. KEATING, M.D.,

ATTENDING OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL, AND PHYSICIAN TO ST. JOSEPH'S AND ST. AGNES'S HOSPITALS, PHILADELPHIA.

I have often been asked to write out my experience with this most distressing complaint. It has been my good fortune to make many voyages, of various lengths, and to come in contact with a variety of people, in all parts of the world; and, though I respectfully submit to the much greater experience of my professional brethren who are in the merchant marine, I think the knowledge one acquires of human nature by a shore-practice often enables one to detect peculiarities in individuals that form strong indications for treatment.

Sea-sickness is a queer symptom; for a symptom indeed it is, having many causes. It will often fight shy of the most delicate individual, and then lay low the boastful traveler who cannot count his voyages on his fingers, and who "never was sick before in his life." It is not, as some would say, a result of imagination, for children are often sick at sea, and sometimes very sick, and animals frequently die of it; nor is it due always to the motion of the vessel, as persons are frequently made ill by the very thought of being at sea, when the vessel is still in the dock. My own opinion is that it is due to two causes: first, one purely reflex, independent of any gastric irritation whatever, due to loss of vaso-motor tone and the occurrence of disturbance in the cerebro-spinal centre as the result of diminished or disturbed arterial tension; or as a reflex from the organs of special senses, especially sight and smell, or the oculo-motor nerve, or the pneumogastric terminals. Of course, the exciting cause of this may occur anywhere, at sea or on shore. Some of these causes are: a shock, a nauseating odor, the motion of a swing, an empty stomach, a sudden change of position —such as rising suddenly from a stooping posture—tobacco-poisoning; and hundreds of other things may cause nausea, which is exaggerated a hundredfold if the person is at sea.

Let us call this variety the nervous form. It is most common in women, and in nervous men overworked mentally. If there is no actual nausea, there is likely to be a feeling of uncertainty, or vertigo may be present,

or a feeling of faintness or of cold. Sometimes the symptoms are giddiness, cold perspiration, or a tight band around the forehead.

This is the form of sea-sickness that is relieved by whatever stimulates the nervous system, increases arterial tension, acts as a sedative by increasing the force and tone of the circulation. We will speak of this more at length hereafter.

The other form I may call the bilious. Bile has, probably, nothing to do with it, unless, perhaps, by constant retching, some bile may regurgitate into the stomach, and add to the nausea and vomiting. The word "bilious" is nowadays used to describe the result produced by a digestive tract which is overloaded with undigested food, and contains mucus, matter undergoing fermentation, and ptomaines, by which we mean poisons resulting from decomposition. These conditions are found in high livers, persons who have overcharged themselves with rich food, drunk to excess, or who are constipated—men who, for a week previous to the voyage, have had parting dinners, or young girls at puberty who are chlorotic, or who are of the bilious type. The least thing, even on shore, would nauseate these individuals; they probably, at all times, wake up with a coated tongue; the thought of breakfast turns against them; their bowels are constipated, the urine scanty and high-colored; they suffer from flatulency, are languid, and life to them looks dark and gloomy; in the language of social science, they are pessimists. Now add to these derangements the motion of a ship, the smells from the kitchen, the steam and the hot oil, and sea-sickness is bound to result. These are the patients that are "so much benefited by sea-voyage." Nature has found a means of opening their safety-valves!

We have here the two classes of persons who suffer from sea-sickness; of course, the classes are not always absolutely separable.

The bilious-nervous temperament is a well-known type; nevertheless, as far as treatment is concerned, it is as well, as far as possible, to distinguish the individual type.

We may divide the treatment into two classes, the preparatory and the actual. Persons who contemplate a sea-voyage should, to a certain extent, prepare themselves for it.

It is a great mistake to use active purgatives, such as the various pills that command a ready sale; these often stir up secretion and bring on sea-sickness, or else they so weaken the circulation and nervous system as to greatly diminish arterial tension.

A day or two of careful nutritious dieting, restful sleep for a night or two before sailing, a daily laxative—preferably a dose of Hunjadi water in the morning, Tarrant's aperient, sal muscatelle, Hathorn (Saratoga), Rubinat water, or an enema at night to unload the rectum—this is infinitely preferable to a mercurial purge, except in the case of a person who has overloaded his stomach, and congested his liver by over-eating, and has possibly been indiscreet in the use of stimulants before sailing. In such a case, a blue pill followed by a dose of castor oil is a necessity.

These directions govern all classes of cases, and are simply matters of common sense.

As regards the special medical treatment, many suggestions have been made by medical writers, and some are of value. The use of bromides has been advocated, in small doses by some, in very large doses by others. Their use is specially advocated for persons of a nervous temperament, in whom it is expected that the bromides (the soda salt agreeing better than the potassium) will control the vaso-motor system and diminish the reflexes. Possibly large doses may have succeeded in some cases, but I fear the remedy is more dangerous than the disease. Others have for several days previous to the voyage advised small doses (ten to fifteen grains) of one of the bromides, along with tincture of nux vomica, five or ten drops. Certainly this treatment can do no harm, and may be tried.

I may say here that I am very much opposed to experimenting in these cases with such a powerful drug as antipyrine. It is a most valuable remedy in severe illness, but a dangerous compound to play with.

The use of caffeine has been highly recommended by some; indeed, a small cup of strong black coffee will often control reflex nausea when nothing else will. The combination of these drugs, associated with the local sedative effects of carbonic acid gas, has become quite popular, and I am sure the valuable preparation of Warner, called bromo-soda (bromide of sodium), and caffeine in granular effervescent form, will become very popular upon sea-voyages. Keasbey & Mattison's bromo-caffeine (the hydrobromate of caffeine) has also been used with success; these may be used for several days preparatory to the voyage. The granular effervescent oxalate of cerium has also

been extolled as a remedy for reflex nausea. The hydrochlorate of cocaine has recently had many advocates; indeed, the preparations of coçoa, including the Vin Tonique Mariani and Thé Mariani, are highly recommended. There are some people who are said to be very susceptible to the use of cocaine; therefore, some caution must be used in its administration. I would begin with the twentieth of a grain at the onset of the voyage, and repeat according to its effect.

We will then take it for granted that, as far as possible, the individual starts on the voyage in good physiological condition; the bowels are free from accumulation, the stomach is at rest and normal, as far as its contents and secretions are concerned. The nervous system has also probably been quieted by refreshing sleep, or soothed by a mild bromide mixture, and the vaso-motor system holds its grip on the circulation, strengthened by an agreeable tonic, such as Vin Mariani with a few drops of tincture of nux vomica, or the elixir of calisaya bark and one-sixtieth of a grain of strychnia sulph. In many cases, all that is required is simply to maintain this condition of health: live on deck in the open air; seek occupation that will be pleasant; enter into the enjoyment of the trip; join in the games, the discussions, the walking-matches, or become the victim of an absorbing novel. Keep away from the smells, and, if you are uncertain of yourself, keep away from the dining-room, and only seek your state-room at night for sleep. I have often seen young women hourly struggling through the first days of a voyage, wrapped up like North Pole explorers, stretched on the sea-chairs with a plate of olives and crackers by them; or, occasionally, this frugal repast is varied with a roasted potato, dry and mealy, with only salt as a condiment, and an occasional sip of champagne, or brandy and cracked ice, or ginger ale. The latter is better and more laxative, if combined with Apollinaris water, and is an excellent stomachic. Mr. F. E. Morgan, of this city, has prepared an elixir of whey, which contains whey, brandy, and suitable flavoring, which make it highly nutritious and stimulating. A wineglassful of this, with cracked ice, I have frequently known to allay gastric irritability from reflex causes and debility. Gradually, then, the circulation will adjust itself to the motion of the ship.

When it comes to the question of diet, a difficult problem is presented. Ships' cooking always, more or less, has unpleasant associations to the voyager who is balanced just on the verge of nausea, and, do what they may in the kitchen, the soups and meats flavor of the ship. On all sea-going vessels, there should be a plentiful supply of the many excellent preparations now given us for sick-diet, such as Valentine's beef-extract, with a little cracked ice and brandy, and Carnrick's liquid peptonoids, an excellent nourishing preparation. Bovinine, when flavored with celery-salt, or Leube-Rosenthal's beef solution, or Rudisch's sarcopeptone. As fresh milk is an impossibility, we could resort to such preparations as Borden's or Canfield's condensed milk, with Mellin's food, malted milk, Carnrick's milk food. All these are very palatable and very nutritious, and certainly a few of them should be found on every vessel carrying passengers

Some individuals give up at once, and require medicinal treatment. Possibly such preparations as the following may be found of service:

℞ Vin. ipecac. . . . . ♏viii
Tinct. nucis vom. . . . . ♏viii
Elix. lactopeptine . . . . . q. s. ad f℥i

M. Sig. Teaspoonful in water every half-hour, or every hour, till half a dozen doses are taken.

Or

℞ Sodii bromid.,
Potass. bromid. . . . . āā gr. xxx
Tinct. capsici. . . . . ♏vi
Syr. zingib. . . . . f℥i
Aquam . . . . . q. s. ad f℥iii

M. Sig. Tablespoonful every hour.

Or

℞ Cocaine hydrochloridi . . . . . gr. ⅛
Acid. nitromuriat. dil. . . . . ♏xl
Elix. pepsini . . . . . q. s. ad f℥ii

M. Sig. Dessertspoonful in wineglassful of water every hour till four doses are taken.

Or

℞ Morphiæ acetat. . . . . gr. ¼
Acid. hydrocyan. dil. . . . . ♏ii
Elix. orang. amar. (rub.) . . . . . f℥ss

M. Sig. Teaspoonful in water every hour till four doses are taken.

Or

℞ Elix. quiniæ, ferri et strych.

M. Sig. Teaspoonful every four hours in water.

But there are some who, notwithstanding all attempts, whether from the want of will-power, fresh air, or medicine, certainly suffer so severely with sea-sickness as to make it imperative for them to remain in their berths. Indeed, even then the disturbance may be so great as to threaten life and to require energetic medical treatment.

For such, an absolute recumbent position

is required, stimulants and food in very small amounts, in the most palatable and nutritious form; cracked ice, which will frequently allay the irritability of the stomach, an ice-bag to the forehead or the nape of the neck or *down the spine*, and counter-irritation to the epigastrium—as a mustard poultice. Indeed, in many cases the hypodermic use of morphia and atropia will often quiet the nervous system and give more relief than anything else. Persons who really suffer to such an extent as this should not be forced on deck; they are far better off, for a few days at least, in their berths, especially if they can get fresh air from an open port-hole. Especially is this the case with delicate women who suffer from dysmenorrhœa. I believe these are especially apt to be sea-sick if their period should come on whilst on the voyage.

Cologne, bay-rum, camphor, aromatic ammonia will often control the reflex from the sense of smell, and should not be forgotten when arranging the medicine-chest for the ocean-voyage.

I have jotted down a few hints in this paper, some of which may be of value, and and most of them have stood the test of personal experience.

Let me add one more observation: there is too much attempt at faulty cooking upon most of the transatlantic steamships. The food is too heavy, too highly seasoned, and difficult of digestion. A clean well-served table, with tempting dishes simply cooked and of sufficient variety, will form an attraction that few steamships possess. As a rule, the tea which is served is good, the coffee atrocious. Very little attention is paid to the preparation of breakfast, and nothing whatever for the average stomach is provided at the last meal. When the patient has reached the stage at which he can take anchovy toast, grilled bone, and Welsh rarebit, he has his sea-legs on.

THREE CASES OF PARTIAL RETENTION OF THE PLACENTA AFTER LABOR AT TERM.

BY CHARLES P. NOBLE, M.D.,
PHILADELPHIA.

Case I.—Mrs. S., æt. 23, has had four children and one miscarriage. She fell in labor April 12, 1886, at 7 A.M.; pains were feeble and infrequent till noon. I saw her at 3 P.M., and found the membranes ruptured and the os dilated to the size of a dollar. Presentation, vertex, L. O. A. Dilatation was slow and painful. At 6.45 P.M. a powerful pain forced the head through the cervix, and delivery was soon completed. The placenta was delivered by the Credé method; more than usual difficulty was experienced. The cotyledons were somewhat separated, but, after a careful examination, which I always make, I considered the placenta entire. A drachm of Squibb's fld. ext. ergot was given, and this was subsequently repeated. I was called the following morning, and found that the patient had passed a restless night; had suffered from severe after-pains; pulse 110. Ergot was continued in smaller doses, and ten drops tr. opii deod. given every two hours. 3 P.M., had slept some; pulse 120; temperature 104° F. Had passed urine naturally. Full doses of quinine were ordered, and the temperature fell to 100°. Until the 16th, the temperature varied from 100° to 102°; pulse from 90 to 110 per minute. The flow was scanty, but not offensive. The treatment was quinine, with poultices to the hypogastrium. The night of the fourth day, the lochia became offensive, when vaginal injections of sublimate solution, 1–4000, were begun, and half-drachm iodoform suppositories ordered. The fifth day, the pulse fluctuated from 85 to 110, the temperature from 101° to 103°; same treatment. Sixth day, consultation with Dr. D. Longaker; pulse 90, temperature 101.4°. Careful digital examination revealed adherent placental tissue, and an unsatisfactory attempt was made, without ether, to remove it. The uterus was irrigated, and an iodoform suppository introduced. Two grains of quinine and half-drachm fld. ext. ergot were ordered every three hours. These manipulations were shortly followed by a chill, with a temperature of 104.2°. Seventh day, temperature and pulse lower, treatment the same. Eighth day, under ether, Dr. L. removed the remaining placental tissue, using his finger as a curette. The uterus was irrigated and an iodoform suppository introduced. In about one hour, the patient had a severe chill, temperature 104°, followed by profuse cold sweats. Ninth day, temperature 101°, pulse 105. She felt well, and was hungry. Quinine in tonic doses, digitalis, and milk punch were given, and vaginal injections continued. On the twelfth day, her pulse was 90, temperature 100°, and they became normal on the fourteenth day. The fetor also disappeared from the lochia, and the injections were omitted. Under the use of Basham's mixture, with strychnia and nourishing diet, the patient rapidly recovered.

Among other points of interest in the case were the absence of special tenderness over the uterus, the ability to pass urine naturally, the chill after intra-uterine manipulation, and the rapid improvement after the uterus was entirely emptied.

Case II.—Mrs. G., æt. 24, primipara, was delivered February 4, 1888. There was nothing of note in the labor. The placenta was expressed by the Credé method. The cotyledons were somewhat separated, but the placenta was considered entire. Slight fever appeared on the third day and continued through the first week. The pulse ranged from 90 to 100 beats, and the temperature never exceeded 101° F. The patient felt fairly well. An examination on the fourth day revealed a fragment of placenta less than half the size of the little finger. This was removed, the uterus irrigated with sublimate solution, and a hundred-grain iodoform pencil introduced. Vaginal injections were continued. There was some fetor during the first few days. Ergot and quinine were used internally. Mrs. G. recovered her strength slowly under Basham's mixture, with strychnia. It seemed remarkable that so small a fragment could cause any disturbance, yet she improved from the day it was removed. The urethral catheter was not used.

Case III.—Mrs. S., already referred to as Case I, was delivered of her sixth child, April 1, 1888. Labor began by rupture of the membranes, was completed in three hours, and presented nothing of note. The placenta was expressed, as in the former labor, with some difficulty. It was considered entire. On the second day, while examining the abdomen, I noticed some fetor, but, as the patient's pulse and temperature were normal, it was attributed to insufficient cleansing. (And here I may say that the plan of examining the abdomen at each visit during the first week, I consider a most valuable one. The adjustment of the binder is a good excuse, if any is necessary. The involution of the uterus can thus be watched, and valuable information gained. It is very easy to hold the nose near the pubes and thus observe any odor of the lochia, and this without attracting the patient's attention.) Sublimate solution, 1–4000, had been employed for washing the genitals, and the nurse, a neighbor, was directed to cleanse them more carefully. On the morning of the third day, there was still no fever, but the fetid discharge continued. An iodoform pencil was introduced into the vagina. In the evening, the pulse was 100, temperature 102° F. The vagina and uterus were at once irrigated and examined. A fragment of placental or decidual tissue, not larger than a bean, was found and removed, and a fifty-grain iodoform pencil was left in the uterus. Fourth day, the pulse was 90, temperature 100°, and the discharge was still fetid. An attempt to introduce the syringe-nozzle within the uterus was unsuccessful and caused considerable pain. A half-soft catheter was obtained and attached to the syringe. The catheter was introduced and the uterus washed out without further difficulty. In about thirty minutes, the patient had a violent chill; pulse 140, temperature 103°. Stimulants were used. In the evening, the pulse was 90, temperature normal. The pulse and temperature became permanently normal after the first week, when the putrid odor likewise disappeared. At no time was urination interfered with. The uterus was irrigated once daily, by means of the catheter; the vagina twice or three times. Internally, ergot, full doses of quinine, and milk punch were given. Basham's mixture and strychnia were ordered later as a tonic. The convalescence was interrupted by an attack of mastitis, which resolved under the roller bandage and rest treatment.

These three cases embrace my experience with partial placental retention after labor at term. Having always exercised great care in examining placentæ, I am convinced that it is not always possible to be assured that the placenta is entire. Where the cotyledons are not separated, and where no fractures in the placental tissue are present, this is, of course, simple. Likewise, no difficulty could be experienced in determining the loss of large fragments. But, where a friable placenta is much fractured and the cotyledons much separated, it is very different, and the absence of small fragments will escape even minute inspection.

The fact that putrefaction of the placental tissue resulted in each case is of interest. The women were both poor, and neither had an efficient nurse. Had strict antisepsis on the part of the nurse and patient been possible, perhaps the patients would have escaped infection and the placental tissue been cast off without putrefaction. However, the relation of non-pathogenic bacteria, so constantly found in the vagina, to putrefaction, is by no means thoroughly understood. In these, as in all other cases, I carefully cleansed and disinfected my hands before touching the genitals; but full

antiseptic precautions were not employed, for the reason that the neighbor-nurses had neither the intelligence nor training to be trusted with agents so potent for harm as well as good. It has been the greatest relief to me, when septic trouble has developed among my patients, to know that I had practiced personal disinfection.

Another point of interest is the chill which so often follows intra-uterine manipulations in septic cases after abortion and at term, especially where infected placental or decidual tissue has been removed. It is not so common after simple irrigation. The effect is, at first, to prejudice one against the method, for the chill and prostration are truly alarming. But observation shows that these apparent bad effects are but temporary, and rapid improvement usually follows the cleaning-out and disinfection of the uterus—perhaps always, if the action has been prompt. While nervous influences doubtless play an important part in the production of the chill, yet it must be admitted that momentarily increased absorption of poisonous material through abrasions caused by the finger or instrument is also a factor. Hence the utmost gentleness, not only during the removal of the retained mass, but in the subsequent irrigations, is of the utmost importance. For the same reason, the finger is the best curette; and, besides, by it alone is it possible certainly to determine that the uterus is empty. Under anæsthesia, it is easy to explore thoroughly the uterine cavity with the finger. Four fingers can be inserted into the vagina, and the uterus depressed from above, if necessary. In discussing these cases, it is unnecessary to consider the propriety of intra-uterine manipulations in the presence of circum-uterine inflammation; but in cases seen early, where absorption of putrid material, and perhaps invasion of the tissues by pathogenic micro-organisms, is taking place from the uterine cavity, there is no doubt of the propriety and advantages of clearing out foreign matter and irrigating the uterus until it is thoroughly disinfected.

The urine was passed naturally in each of the three cases. From a diagnostic point of view, this fact is of importance, as it points to the uterine cavity as the seat of absorption of septic material. During the first and second days, urination is often prevented by tumefaction of the urethra, caused by pressure of the head during a delayed second stage. Some days later, it may be interfered with by the pain caused by straining where circum-uterine inflammation or marked metritis is present. But retention of urine, occurring from the second to the fourth day, is almost always due to septic endocolpitis. Hence, when septic fever begins at this time, and urination is normal, the vagina can be almost excluded as the point of absorption.

In each of the three cases, after-pains were sufficiently marked to attract attention, especially in the first case, in which the largest mass was retained.

In these cases, the fever was due to putrid infection rather than to invasion of the tissues by micro-organisms. It is in cases of putrid infection that early local treatment gives especially brilliant results. The treatment of Case I, during the first few days, is an example of what should not be done. In no other class of cases is an early diagnosis of more importance, nor are temporizing measures likely to lead to more serious consequences.

ANTIPYRINE AND ITS USES.

BY HARVEY B. BASHORE, M.D.,
WEST FAIRVIEW, PA.

Dimethyloxyquinizine is a complex substance derived from chinoline. Its more common name of antipyrine is that under which the German manufacturers hold their copyright. It is sometimes adulterated with benzine and phenylhydrizine, but the pure drug is easily distinguished, as it does not change litmus-paper, while the impure does. It is very soluble in water and alcohol, and is best administered by dissolving it in half a glassful of ice-water, the dose being from 3 to 30 grains; or it can be given hypodermically when a very rapid effect is desired. Its *physiological action*, according to Denian, is very complicated—in large doses it may produce constipation, is quickly absorbed by the mucous membranes of the intestines, and is eliminated by the skin, kidneys, and intestinal glands. In large doses, it dilates veins and capillaries, and from this cause its antipyretic effects are partly due: it is said to modify the heart and circulation, and on the nervous system has a decided action. The effect on nutrition is to diminish general disintegration, and particularly disintegration of nitrogenous materials. The therapeutic action I have arranged under various headings.

(1) *Antipyretic.*—Pavy administers it with good results in the following manner: If the temperature is 103° F., he gives 30 grs. in 10-gr. doses every half-hour; if 104°,

he gives 45 grs. in 15-gr. doses every half-hour; if 105°, 60 grs. in 15-grain doses every half-hour. Hamilton, in his India practice, gave 30-gr. doses when the temperature was as high as 104°; if, after an hour, the temperature was 101.2°, he gave the same, and, after another hour, he gave a small dose, if the temperature was 100°.

He reported no evil effects from its use. In heat-stroke, hypodermic use of the following solution is very satisfactory:

℞ Antipyrini . . . . . ℥ii
Aq. dest. . . . . q. s. ad f℥ss
M. Sig. ♏xx = gr. x.

Burtzeff, in his observations, claims (1) that antipyrine is inactive in malarial fevers; (2) that doses of 30–50 grs. lower the febrile temperature 0.5°–2.8° (Centigrade), the fall lasting from five to eight hours; (3) that it sometimes causes nausea, vomiting, and drowsiness.

(2) *Analgesic.*—Dr. White, of the Charity Hospital, has found great relief in headache by giving a single dose of 15 grs. The relief generally comes in about half an hour. He says a sense of drowsiness ordinarily supervenes, followed by a brief slumber, and the patient awakens quite relieved from distressing symptoms.

At St. Bartholomew's Hospital, twenty-six cases of migraine were treated with antipyrine, with great satisfaction in each case, although the dose did not exceed four grs. Generally relief was obtained after giving the second dose of three grains half an hour after the first.

Professor Sée had equally good success, drawing his conclusions from forty-two cases of migraine, in each of which he administered fifteen grs. at the onset of the attack, and fifteen grains one hour later. Usually, the pain disappeared in from twenty to thirty minutes after the first dose, the second acting the part of a preventive. In cases of facial neuralgia, his results were also very gratifying, the treatment being seventy-five grains per day in five doses of fifteen grains each. He also used, in various cases, hypodermic injections of 7½ grains in 22½ grains of water, adding one-sixth gr. of cocaine to each injection.

Intercostal neuralgia is reported to have been cured by giving ten-grain doses three times a day.

In headache, Lyman used an initial dose of fifteen grains, repeated every two or three times if necessary.

In acute and subacute rheumatism, Clement found that antipyrine did much good in those cases in which salicylic acid was of little use, and that it was innocuous even in cases of cardiac and renal trouble, but of no value in chronic rheumatism.

In colicky pains of the stomach, antipyrine injections can be substituted for morphine, with very good results.

(3) *Hæmostatic.*—To control hemorrhage, Hénocque uses antipyrine in powder or solution. In epistaxis, the powder can be snuffed up the nose; for hemorrhage from the uterus, it can be applied to the cervix or to the cavity; for wounds in general, he uses a five per cent. solution. Dr. Powell used a four per cent. solution on wounds, and had excellent results.

Dr. Groetz, of Geneva, used it in three cases very successfully, both in solution and in powder.

(4) *Phthisis.*—Dr. Zahrzhevski used it in the Helsinfors Hospital, preferring the hypodermic administration. In the case of a man fairly robust, it required ninety grains to produce the best effect, while in greatly debilitated cases from ten to fifteen grains were sufficient.

Dr. Daremberg says that consumptives may use from 48 to 96 grains daily for months with exceedingly good results.

Dr. Dujardin-Beaumetz cautions against too large a dose in phthisis, considering eight grains sufficient.

Sakrsheroski claims that the hypodermic use of from ten to fifteen grain doses, continued for a considerable length of time, produces marked beneficial results.

(5) *Labor.*—Dr. Queirel claims that it calms the excitement and lessens the pain, being most beneficial during the first stage, and that it does not interfere at all with the progress of labor. He administers it hypodermically, in doses of four grains, giving a second in two hours if the first does not produce the desired effect.

Professor Chian draws conclusions from twelve cases that it has no effect on pregnant women other than that of an antipyretic.

Toxicology.—In one case of enteric fever, a thirty-grain dose was followed in about four hours by a fall of temperature from 104° to 95°, accompanied by alarming collapse, sighing respiration, cold extremities, clammy surface, and feeble pulse; under stimulation, the patient quickly recovered.

In a case reported in the London *Lancet*, a woman, 67 years old, was given 37½ grains per day for eight days, when the skin of her arms became covered with erythematous patches, her eyes became uncomfortable, and her feet were icy cold. Neither nausea

nor giddiness was present. The next day, her face was red and extremely swollen, and the rash became very general. This condition gave rise to no suffering, and there was only slight itching; but the patient felt as if "the inside of the body was filled with ice." The symptoms gradually disappeared upon withdrawing the drug.

In another case reported by the *Lancet*, there was swelling of the body and also of the inside of the throat, which was obstructed to such an extent that for six hours she was threatened with suffocation. The skin was covered with red spots, without itching, and the perspiration dripped off the extremities of the fingers.

The chief benefits of antipyrine seem to be those derived from its action as an antipyretic, an analgesic, or a hæmostatic. When carelessly used, it may seem to be valueless, or even worse than valueless; but, when rightly used, it promises to be a drug from which we can expect brilliant results.

MIXTURE OF IODINE, IRON, POTASH, SALICYLIC ACID.

BY J. B. JOHNSON, M.D.,
WASHINGTON, D. C.

The following is the manner in which I form a combination of iodine, iron, potash, and salicylic acid:

No. 1.

℞ Tincture of iodine . . . . . f℥j
Distilled water . . . . . f℥vj
Chloride of potassium . . . . . ℥j
Mix and dissolve.

No. 2.

℞ Distilled water . . . . . f℥ii
Bicarbonate of soda . . . . . ℥i
Salicylic acid . . . . . ℥ii
Sol. of citrate of ammonia . . . . f℥ix
Tinct. chloride of iron . . . . . f℥ii
Glycerine . . . . . f℥ii
Distilled water . . . . . q. s. ad f℥vj
M.

This No. 2 mixture should be carefully made in an eight-ounce graduated glass measure; and, when prepared, should be added to formula No. 1. By this adding of formulas Nos. 1 and 2 together, a beautiful wine-colored solution is produced, which is by no means unpleasant to the taste. The mixture may be made more elegant by the addition of six fluid drachms of elixir of orange, or twenty drops of oil of gaultheria. The dose is a tablespoonful after eating. I use this mixture, with great advantage, in all cases of a strumous and debilitated condition, requiring an alterative and tonic for their treatment. By adding fifteen grains of bromide of potassium to each dose, and its use commenced about ten days before the expected period, I have found this mixture to be the best I have ever used in the treatment of painful menstruation. I have found gleet to yield to the use of this mixture more rapidly than to any other medicine, especially if the bromide of potassium is added in suitable doses. In cases of disorders of the stomach, attended with fermentation of the food, it acts well if taken a half-hour after each meal. It acts well in removing lithate of ammonia from the urine, and forms a most excellent tonic for children if given in teaspoonful doses every four hours.

A CASE OF HYDROCEPHALUS.

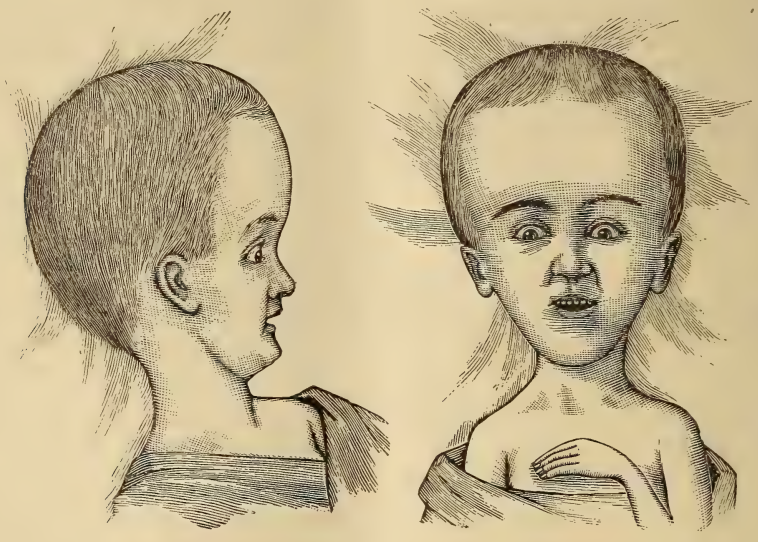
BY WILLIAM B. DEWEES, M.D.,
SALINA, KANSAS.

Albert Fechtig Pitzer, son of Phillip T. and Margaret D. Pitzer, was born May 5, 1879. He was the tenth child born of his mother, who experienced nothing unusual during the gestation and delivery of this son, nor was there anything unusual in the child's appearance at birth, excepting an overlapped condition of the parietal bones in the inter-parietal or sagittal suture. The child did apparently well until one week after its birth, when it was seized with convulsions, the attacks succeeding each other so rapidly that the mother counted over a hundred in a few days, and ceased to keep record of them; they continued for several weeks, and then quit for a week or more. Exactly four weeks after the beginning of the first attack, a second series of convulsions began, continuing about the same length of time, but leaving the child paralyzed (hemiplegia) on the right side for over one week. Precisely four weeks from the beginning of the second attack, a third series followed, this time leaving the child's left side paralyzed for over a week, the child lying in a comatose condition for twenty-four hours after the convulsions ceased before it commenced to show life by moving its limbs, etc.

Four weeks, to the day, following the beginning of the third attack, a fourth series began, this time leaving the child paralyzed bilaterally for several weeks. From this time on, his head began to enlarge, and convulsions continued at irregular intervals

up to the present day (July 12), the child having one in a week, or one in a month, and sometimes as often as three or more a day. He has always slept well; he eats well, but his bowels never have moved, with but few exceptions, since his birth, unless by artificial aid, cathartics, clysters, etc. The parents have noticed that every fall in the year, when the cow (the milk of which is fed to the child) is allowed to eat *ragweed* (*ambrosia trifida*), that this has the effect of moving his bowels for several days or more, regularly, but that this is the only thing that they have discovered thus to relieve him.

The child has never manifested any intelligence, and does not recognize anything, not even when looking at an object. It gives expression to a little noise when it hears its father's voice, and also seems to recognize by similar noises when its mother talks; it also quiets down when the mother speaks to it, saying "Now, my good boy, be quiet, and mother will bring you something good to eat." It never manifests any signs of hunger or thirst, but will eat and drink whenever food is offered. Its head now measures twenty-eight and a half inches in circumference, occipito-frontal measurement. As to the family history, there is consumption on the mother's side; history upon the father's side good. The mother now has had eleven children (one being born since this boy), the first five of which died when from one to five months old; in all, seven are dead. The mother is 38 years of age, and the father 43 years.



Society Reports.

PHILADELPHIA CLINICAL SOCIETY.

Stated Meeting, June 22, 1888.

The President, Dr. Mary E. Allen, in the chair.

Dr. Amy S. Barton read a paper entitled

A Case of Placenta Prævia, followed by Purulent Endometritis.

J. M. presented herself at my office November, 1880, with the following history: Married seven years; has one child, six years old; has never been well since the birth of child. Upon examination, I found a stellate laceration of cervix uteri, the rents being bilateral and posterior; lips everted and covered with exuberant granulations. Perineum lacerated, with prolapse of posterior vaginal wall. Patient's general health poor. Under ordinary local and constitutional treatment, the condition was improved sufficiently to warrant an operation; accordingly, I performed trachelorrhaphy, fourth month, 6th, 1881, uniting only the two lateral fissures. This was followed by perfect union. On the tenth day, I removed the stitches and restored the perineum, which united nicely, the patient making a good recovery. I was subsequently engaged to attend this woman in confinement, November 26, 1882. Early in the evening of the 23d, a hasty summons was sent for me, but, being out of my office, I did not reach the house until 8 P.M. I then learned from the

excited bystanders that at 4 P.M. the patient, when she was rising from a nap, passed a small quantity of blood, without any uterine pain. She immediately dressed, went downstairs, and prepared tea for herself and family; while doing this, she tripped over a brush on the cellar-stairs, but did not quite fall. About 6 o'clock, after taking her seat at table, while perfectly free from pain or any local sensation whatever, she was seized with a violent hemorrhage. How much blood was lost I am unable to state, as it had been scrupulously cleaned up before my arrival. I can only testify that the clothing—a heavy flannel wrapper and her skirts — was thoroughly saturated. The patient walked upstairs, stood while her clothing was changed and bed prepared, then fainted as she lay down. At this time the hemorrhage ceased. When I arrived (at 8 P.M.), I found the patient rallying from the shock, but very pale and weak. No hemorrhage; os uteri soft; dilatation just commenced; fœtal pulsations good. Gave a suppository containing extract belladonna gr. ss., pulv. opii gr. i, brandy by the mouth, and awaited results.

At 10 P.M. another hemorrhage occurred; moderate in amount. The patient had a nervous chill, shaking violently; pallor was extreme, and she looked as though dying. I immediately made another examination per vaginam; found the placenta on the lower segment of the uterus, to the left side, covering the open orifice of the os uteri. By passing my finger well to the patient's right, the border of the placenta could be reached, but in no other direction could the border be felt. I at once applied a tampon, which checked the flow, and, after the administration of brandy, the patient soon rallied.

I now sent for Dr. Hannah T. Croasdale, who arrived at 11 P.M., at which time the patient was comfortable; no uterine contractions of any moment. At midnight, the fœtal pulsations were good, even vigorous, and the patient was doing apparently well. We determined to await further dilatation before attempting to extract. In our judgment, the operation of turning, at that time, would subject the mother to imminent risk from hemorrhage, and there was not sufficient dilatation for the use of forceps.

I had administered quiniæ sulph. gr. x at 11 o'clock, which had been vomited. At midnight, the dose was repeated, with the same result. Repeated doses of fluid extract of ergot were given; the dose was sometimes retained for half an hour, but was generally vomited. There were occasional slight uterine contractions, no doubt resulting from the small amount of the drug which was retained.

The patient dozed, at intervals, between midnight and 2.30 A.M. Pulse feeble; nausea extreme. Owing to the extreme prostration, and the fact that there was no return of the hemorrhage, I deemed it improper to disturb her by listening for fœtal pulsations, thinking, because the fœtus had survived the last hemorrhage for two hours, it was safe until another occurred. I was shocked at 2.40 to find the pulsations were gone. The cervix had relaxed and shortened sensibly during the last three hours. We decided to etherize immediately, and deliver with forceps, if possible; otherwise, by turning.

I introduced my right hand, pushed the placenta away, to the right, and found the membranes unruptured. I ruptured them, and found no difficulty in applying the forceps to the head, which presented in the first position. It was still above the superior strait. The head was brought down to the perineum without difficulty, other than the use of considerable force. The perineum reached, it seemed impossible for the head to pass the vulvar orifice without lacerating the soft parts. We, accordingly, made lateral incisions of the labia, removed the forceps, and enucleated the head, making pressure through the posterior portion of the perineum and rectum. Just after the delivery of the head, the abdomen suddenly enlarged at the umbilicus. An attempt was made to deliver the body rapidly, but this was found impossible. My hands having become fatigued, I requested Dr. Croasdale to deliver the body for me, which she did with difficulty, it seeming too large to pass the vulvar orifice. Immediately after the removal of the child, I passed my hand into the vagina and brought away the placenta, which was entirely detached. There was no hemorrhage, and the uterus was well contracted. The peculiar appearance of the abdomen suggesting internal hemorrhage, I insinuated my fingers, and finally my whole hand, into the uterus, and found it empty. In a moment it relaxed, but responded promptly to the stimulus of hot water injections. There was no hemorrhage after this, and the patient rallied well from the ether and shock.

The perineum was not lacerated at all, and there was but slight laceration of the cervix, anteriorly; not sufficient, in our opinion, to justify the immediate operation,

considering the patient's condition. It is worthy of note that the laceration did not occur in the line of the old cicatrices, which were on each side

The child weighed 12½ pounds, the body being disproportionately large. The mother's weight, in health, is 90 pounds.

While I was attending to the mother, Dr. Croasdale made every effort to resuscitate the child, using hot and cold water alternately, artificial respiration, etc., but without avail.

The patient did well until the third day after delivery, when her temperature rose to 100°, pulse to 120. As this was coincident with the establishment of the lacteal secretion, it was supposed to be due to that, as there was no abdominal tenderness whatever. There was slight distension from flatulence, but this was entirely removed by having the bowels freely evacuated, and after this date an evacuation was secured each day by enemata.

The lochia, though diminished in quantity, were normal in character until the fifth day after delivery, when patient and nurse complained that they were offensive. This I believed to be an exaggeration, as I could detect no odor in the room other than a heavy perfume of white rose, which they persisted in using, contrary to my wishes. Although believing that a serious odor could not be covered by a perfume, I ordered the addition of carbolic acid to the vaginal injections which were being given twice daily, and had the number of injections increased to four a day.

The temperature still kept up to 100°, and that fact, as well as the odor of the lochia, caused me some uneasiness; still, I refrained from making a vaginal examination, lest I should interfere with a possible union of the lacerated cervix.

Three days later, the eighth after confinement, as the patient was not improving, I made a digital examination; found the os closed and slight uterine tenderness. The examination gave no pain at the time, but it was followed by soreness during the next twenty-four hours.

There was no continuous vaginal discharge, but an occasional copious flow of fetid pus. A thorough syringing, with free ventilation, restored everything, apparently, to good order. Hence my failure to detect the odor for several days. I decided to expose the os uteri through a speculum, and then explore the uterine cavity. I found the cervix looking healthy, the laceration united on its inner margin, the external or vaginal surface granulating, bleeding when touched. Fearing I should rupture the united portion, I very cautiously passed a small piece of cotton, on the dressing-forceps, saturated with tinct. iodine, into the uterine cavity. Instantly, out gushed about half an ounce of fetid pus into the speculum. Removing this with absorbent cotton, I passed a fresh piece of cotton into the cavity, which was followed by as much more thin watery pus, the first being thicker. Carefully removing this, I again made a free application of tinct. iodine to the uterine cavity, which now appeared to be clean. After this, I irrigated the cavity once daily with a weak solution of iodine, using a quart of warm water and about one drachm of tinct. iodine.

I found pus in decreasing amount each day, until, on the sixth day from the institution of this treatment, the uterine cavity was found clean. During this treatment, there was uterine tenderness, but no abdominal distension or general soreness. The patient improved in general appearance and appetite, the pulse and temperature sank to normal in about three weeks, and a normal state of health was regained.

This condition of the endometrium may have started from the laceration of the cervix, or the uterine tissues may have been injured by the forceps during delivery.

MARY WILLITS, M.D.,
1527 Green Street. *Reporting Secretary.*

SPECIAL CORRESPONDENCE.

MEDICAL JOTTINGS FROM THE OCCIDENT.

On Board Steamship Mariposa.

I was fortunate in finding, on board the vessel, Dr. Brodie, of Honolulu, on his way home to the islands after a brief visit to the States. He came out from Montreal about eight years ago, and has become very successful in the Hawaiian Islands. Besides a large private practice, he is surgeon to the Queen's Hospital, and port physician of Honolulu. The hospital is partly endowed. The kingdom allows $6000 a year, and a tax of two dollars on all who intend to stop any time in the kingdom is applied to the hospital fund. Shortly before the steamer arrives at port, the purser goes the rounds, giving Honolulu passengers a passport, and collecting the two dollars.

Placed just within the north tropic zone, latitude 21° 18′ N., the islands enjoy a

climate at once moderately warm and wonderfully equable, the thermometer never going higher than 90°, never less than 60°. Being within the trade-wind belt, the group is favored by pleasant breezes for the greater part of the year. Dr. Brodie says bronchial and digestive troubles are what he is chiefly required to treat. Eruptive fevers are seldom met: ten years since any measles; eight years since a case of small-pox. Honolulu has about 22,000 people; probably twelve physicians. One-half of the population employs so-called native physicians, who do not give medicine, unless some native herbs, but depend on prayers and pow-wows for healing-powers. By law, the natives are admitted free to the hospital, if they desire to enter; all others must pay from 60 cents to $2.50 a day, the highest price being for private rooms.

Erysipelas after operations is scarcely known. Antiseptic surgery is not practiced beyond ordinary cleanliness. The natives recover after most horrible wounds or terrible operations—they suffer no more from shock than the ordinary animals of the field. Dr. Brodie said a young native was disemboweled by a bull; the bowels were washed in a bucket of water, replaced, abdomen sewed, and, contrary to his expectations, the boy made a rapid and perfect recovery.

The medical fees are $2.50 a visit in town; $1.00 office-visit, supplying the medicine. The average fee is below what is obtained on the American coast.

Our ship surgeon is Dr. Giberson, a graduate of Jefferson Medical College, in 1876. He is a member of the California State Medical Society, and a gifted writer upon medical jurisprudence.

A son of the late Prof. Trousseau, of Paris, is a practitioner in Honolulu, and enjoys, with Dr. Brodie, the cream of the practice there. Almost all the islands of the group have resident doctors. Dr. Campbell, Dr. Craddock, and Dr. Smith are on Kanai; Dr. Herbert on Mani; two or three on Hawaii. If any of the readers desire information of any kind concerning the Hawaiian Islands, Dr. Brodie, of Honolulu, will be pleased to correspond with such. The death-rate among the whites in Honolulu is 6 or 8 per 1000; among the natives, 30 to 40. They are rapidly dying off.

C. C. VANDERBECK, M.D.

—Dr. Samuel Myers, of Newville, Penna., died August 16. He was 60 years old.

PERISCOPE.

Œsophagotomy for the Removal of a Tooth-brush.

At the meeting of the New York Surgical Society, May 23, 1888, Dr. Lewis J. Stimson presented a bone-handled tooth-brush, six inches and three-quarters long, which he had removed by œsophagotomy. The patient was a spare man, forty-eight years old, who had been under restraint for a few weeks because of mental depression, and who in a moment of suicidal aberration had swallowed the tooth-brush, bristle-end first. The swallowing had been done so quietly and had caused so little inconvenience that the attendant had not been aware of it until informed by the patient two hours later. Dr. Stimson saw him ten hours later, and could touch the upper end of the brush with a sound at a point about seven inches beyond the incisor teeth, say one inch below the cricoid cartilage. The patient had entirely recovered from the suicidal impulse, was anxious to be relieved, and bore the explorations with much fortitude and calmness. Palpation of the neck gave a little pain, but the presence of the brush could not be thus detected. After a few cautious unsuccessful attempts to catch the handle with œsophageal forceps, ether was given and œsophagotomy done upon the left side, the œsophagus being reached below the thyroid gland. A longitudinal incision large enough to admit the finger was made in the œsophagus, and through it the handle of the brush could be felt lying with its breadth in the mesial plane; it was easily caught with an artery forceps and drawn out. The only vessels that required to be tied were two that had been divided in incising the skin. The opening in the œsophagus was closed with a short continuous catgut suture and a single additional stitch at the upper end, where it was noticed that air escaped in coughing. These sutures included the mucous and muscular coats; a second row of interrupted sutures was placed in the fibrous outer sheath, with the hope of thereby permanently shutting off the deep ones from the rest of the wound. The external wound was closed with catgut and silkworm-gut sutures about a large split drainage-tube, which reached to the immediate neighborhood of the incision in the œsophagus. The patient was fed with milk in small quantities at a time, about three pints daily, with an occasional milk-punch. He complained only of a sore throat for a

few days, and at no time did he have any fever. The dressing was changed on the fourth day; there was a slight discharge, decidedly offensive in odor, and the wound was gently syringed with a bichloride solution. On the sixth day the discharge was still scanty and almost free from odor. On the night of the seventh day, during a fit of coughing, the patient felt air pass out through the wound, and on the following day the dressing became quite wet with the milk which he swallowed. He was then fed twice a day through an œsophageal tube, but was allowed to drink a little water when he wished it. Occasionally he would feel the milk regurgitate from the stomach and escape in very small quantities through the wound. This happened for the last time on the eleventh day, and air escaped for the last time on the morning of the twelfth day. On that day he drank a glass of water in Dr. Stimson's presence without feeling it in the wound, and, as cool water syringed into the wound could not be felt in the œsophagus, it was thought that the opening was sufficiently closed to justify shortening of the drainage-tube. On the fourteenth day it was again shortened, and on the sixteenth day it was entirely removed. On the day of the meeting, the seventeenth day, there remained only a shallow opening in the skin.—*New York Med. Journal*, June 30, 1888.

Bursa Pastoris.

In a recent number of the *Deutsche Medizinal-Zeitung*, Dr. Von Ehrenwall, of Ahrweiler, records the results of his investigations into the virtues of bursa pastoris, or shepherd's-purse, as an hæmostatic agent. This common plant, during the fifteenth, sixteenth, and seventeenth centuries, was much prized among the country people in many parts of Germany on account of its supposed power of arresting hemorrhage. It was first brought accidentally under his notice about four years ago while treating a case of menorrhagia that defied all the means employed. A neighbor of the patient advised an infusion made of the common shepherd's-purse, and he accordingly had some of the weed collected and a strong infusion made and given to the patient, whereupon the bleeding ceased immediately after the first cupful. Since then he has repeatedly used it in all forms of hemorrhage, and with such marked success that he considers it the most reliable of all our hæmostatic remedies. He found that the infusion of the dried plant was inert. The fresh plant is the best, in the strength of half a handful of the upper half of the plant to two teacupfuls of infusion. The patient is to take two teacupfuls of the cooled infusion morning and mid-day. If the second dose were given too soon, difficulty of breathing, headache, and vomiting resulted. A pharmacist, Herr Bombelon, of Bael Neuenahr, at his request prepared a fluid extract, a teaspoonful of which, taken three times a day, produces the effect of four teacupfuls of the infusion. The efficacy is said to be due to an acid—bursuric acid—the presence of which in the plant has been determined. The alkaline salts are said to possess the same styptic properties. As these salts are very soluble, he proposes to test them by way of subcutaneous injection, and to report on their action at a subsequent occasion.—*Medical Press and Circular*, June 23, 1888.

Variolous Periostitis.

At the meeting of the Société Médicale des Hôpitaux, of Paris, May 25, 1888, M. Barie read a communication upon variolous periostitis; the following are the conclusions which he reached: 1. Periostitis should take its place among the numerous complications of variola; but, if one may judge by the rarity of published cases, it seems infrequent. 2. It arises during convalescence from variola, generally from the fourth to the sixth week, and appears preferably in adolescents, or young adults who have not yet completed their growth. 3. It may be limited to a single bone, or invade several non-contiguous points of the skeleton. 4. Variolous periostitis occupies the long bones generally at the point of junction of the diaphysis with the apophysis; it has a marked predilection for the bones of the lower limbs, and especially for the tibia. 5. The disease is characterized by a spontaneous pain, more or less acute, increased by pressure and motion; and by a marked swelling of the affected region, in which deep puffiness in immediate connection with the subjacent bone can be detected. The skin preserves its usual aspect and its normal color. 6. The affection is without fever, and terminates by resolution in a space of time varying from about two to six weeks. It may leave behind it more or less persistent periostosis. Relapses are not at all rare. 7. The treatment of the disease is very simple. The affected limb is to be put at rest, enveloped in emollient poultices; in other cases, blisters or some resolving plasters may be employed. These measures suffice to ensure recovery. 8. The disease

is due directly to the infectious agent which causes all the other clinical manifestations of variola; it is occasioned by fatigue which necessarily accompanies the first steps, by walking, or simply by the erect posture. 9. The characteristics which have just been enumerated belong to what may be called the subacute or still benign form of the disease. Analogy with the infectious periostitis occurring in other diseases, as typhoid fever, permits one to suppose that there also exists a grave form terminating often by suppuration with osteitis, necrosis, and even osteo-myelitis.—*Bulletin Médical*, May 27, 1888.

Tension, as met with in Surgical Practice.

In his first lecture (*Lancet*, June 23, 1888) before the Royal College of Surgeons of England, Thomas Bryant, Hunterian Professor of Surgery and Pathology in the Royal College of Surgeons, said that the word "tension," as employed in surgical work, and especially in clinical work, most frequently means the pressure brought about by the stretching or distension of tissue from either the growth of some neoplasm or the effusion of some fluid. In this sense, it means the distension or stretching of parts by a force acting from within—by centrifugal pressure, as it may be rightly termed. But it is, he says, applied in another way; that is, to the stretching of tissues which have been divided and brought together by sutures, the strain upon the sutures from the elasticity of tissues being the measure of the tension.

The effects of tension will, he says, be found to vary according to the nature of the tissue subjected to its influence. In one of an elastic kind, which yields readily under distension, the effects of tension are neither much felt nor well displayed, unless the expanding or distending force is carried to its full extent; whereas, in a tissue which is unyielding and inelastic, the mildest distending force is resented, and the effects of tension are forcibly demonstrated. Again, when the distending or stretching medium acts *rapidly*, the tension brought about in the tissues is severe, the symptoms associated with it are serious, and its effects destructive. On the other hand, when the distending, stretching, or straining medium acts *slowly*, tension is seen acting at a lower level, its symptoms are modified in intensity, and its effects qualified. As a general rule, the severity of the effects of tension, as well as the severity of the symptoms which characterizes its different degrees, is found to turn upon the acuteness of its action and the elasticity of the tissues implicated. To this rule, however, there are exceptions.

The *ultimate* effects of tension upon any tissue turn then, he says, upon the elasticity of the tissue and the rapidity with which the tension has been brought about; but they are invariably destructive. Its *immediate* effects are primarily upon the circulation, especially the venous; and the pressure from within of necessity tends to bring about first a slowing of the capillary blood-current through the stretched parts, and, later on, its stagnation, from which the death of tissue follows.

The one subjective symptom of tension is pain, which is always found to vary with the degree of tension to which the tissues are exposed, and the quality and quantity of the nerve-supply to the part.

As to the diagnosis of tension, he says that in superficial structures it may, as a rule, be readily estimated by palpation. In deeper parts, this may be difficult; in bone or in the cranial cavities, it is impossible. The aspect of a tense tissue helps diagnosis; its palpable enlargement as compared with the opposite and unaffected part, and its stretched appearance, being suggestive. In such a joint as the knee, this condition can be well observed. But when the tense tissue is well covered with soft parts, as in a femur the seat of periostitis, this observation cannot be made; but even there the enlargement of the part, and the engorged veins visible upon its cutaneous surface, are of diagnostic value as indicative of deep pressure.

Mr. Bryant reports a number of interesting cases which illustrate the various ways in which tension may occur, and their diagnosis and proper treatment.

He concludes his second lecture (*Lancet*, June 30, 1888) with the following propositions: 1. The pain associated with every form of inflammation of the bone or of its periosteal covering is due to tension, and the severity of the pain is a fair measure of its intensity. 2. In acute inflammation of the bone or of its periosteum, tension is the chief cause of necrosis; and, in the subacute and chronic forms, it is a potent cause of their chronicity as well as of the destructive changes which, as a rule, follow. 3. The relief of tension, wherever met with, when the result of inflammation, is an important principle of practice which should always be followed. In bone, the principle is most imperative, on account of the difficulties

under which natural processes act in that direction, by reason of the absence of elasticity or yielding in bone, and by reason of the anatomical arrangements of its vessels, which favor blood-stasis. 4. To relieve tension in the softer tissues of the body, the local application of leeches, local or general venesection, acupuncture, aspiration, punctures, and incisions may be requisite; whereas, to carry out the same practice in endostitis or periostitis, subcutaneous or open incisions down to the bone, and the drilling, trephining, or laying open of bone by a saw, may be required, the choice of method having to be determined by the requirements of the individual case. 5. In the early or hyperæmic stage of inflammation of bone, before destructive changes have taken place, experience seems clearly to indicate that the relief of tension—as indicated by a dull aching pain, etc.—by means of drilling or trephining into bone, may arrest the progress of the disease and help toward a cure by resolution; whereas, in the exceptional cases in which this good result does not take place, suffering is saved and destructive changes are limited. 6. In articular ostitis of every kind and variety and in every stage, this mode of treatment cannot be too strongly advocated, as tending toward the prevention of joint-disease. 7. In acute or chronic abscess of bone, diaphysial or epiphysial, the abscess-cavity must be opened as any other of the soft parts, drained, and dressed in the most appropriate way—the principles of treatment being the same in hard or soft tissues, although they are modified by the anatomical conditions of the parts.

Displacement of the Semilunar Cartilages of the Knee-joint.

Dr. W. J. Rothwell, in a communication to the *Denver Medical Times*, July, 1888, gives the following symptoms and treatment of this affection: The symptoms of this luxation come on suddenly, and are well marked. The pain is severe, often excruciating. The limb cannot be extended, but is held semiflexed. The only condition with which the injury can possibly be confounded is that described under the head of movable bodies or floating cartilages within the knee-joint. Here the analogy is so close as to demand the exercise of our best powers of discrimination. In the suddenness of its occurrence, the atrocity of the pain, the inability to move the limb, the conditions correspond very closely. The strongest differential points are: 1. Displacement of the semilunar fibro-cartilages—especially for the first time—requires a considerable degree of violence, while movable bodies within the joint may at any moment produce the most painful sensations without any assignable reason. 2. Movable bodies within the joints must be preceded by a history of synovitis or other disease, which caused the deposit of fibrinous or cartilaginous material of which they are formed; no such history is a necessary antecedent of semilunar displacement. 3. Although a movable body is somewhat difficult to detect and isolate—from which characteristic the Germans call it *ein Galenkmaus*, or a joint mouse—yet it is seldom that it can elude the skilful search of the surgeon. 4. The painful point in semilunar displacement is on the inner surface of the knee, along the border of the inner cartilage, while in movable bodies the location of this point is variable.

Reduction of this displacement is performed by extreme flexion of the knee, thus liberating the imprisoned cartilages, and then rapidly extending the limb. The most important point in the after-treatment is rest, to favor union of the torn coronary ligament. If this precaution is not observed, and the rent remains, the knee-joint is greatly weakened and the displacement is likely to occur again and again. I know of two cases in which complete recovery followed a pretty sharp attack of inflammation of the knee. The enforced rest of the limb and the exudation of plastic material during the inflammatory attack must have healed the breach in the torn tissue. For those cases in which there has been a frequent recurrence of the trouble, if it can be ascertained that it is due to relaxation of ligaments, massage or electricity is beneficial, in fact curative. For those cases of frequent displacement dependent on an unhealed ligament, flannel bandages and various forms of knee-caps are recommended. I have used them with some misgiving, lest they should do more harm than good. The results have never been satisfactory.

—At the Convention of Executive Health Officers of Ontario, at Lindsay, August 14, papers were read by Dr. Coventry, of Toronto; Dr. Yeomans, of Mount Forest; and Dr. Charles N. Hewitt, of Minnesota. The last paper was on "Practical Suggestions on International and Interstate Co-operation for the Prevention of Disease and for Stamping out Epidemics."

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.25**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

ETIOLOGY OF SUMMER DIARRHŒAS IN INFANTS.

The etiology and prophylaxis of the summer diarrhœas of infants are subjects of the greatest importance, not only to the physician, but also to the sociologist. The truth of this statement becomes apparent when we recall the fact that one-fourth of the human race dies before reaching the age of two years, and that a large percentage of these deaths is due to diarrhœa. Recent investigations, with reference to the causes of summer diarrhœas of infants, have been limited practically to a study of the effects of high heat and of micro-organisms. The antiquity of the term "summer complaint" shows that the conception of the relation between high temperature and diarrhœa is by no means new. It is not so much the fact, as the *modus operandi* by which summer temperature causes diarrhœa, that has received attention.

Since diarrhœas are far more prevalent among infants reared in cities than among those in the country, heat has been recognized as a predisposing or mediate, rather than as a direct, cause of diarrhœa; and since diarrhœas are most common among the children of the poor, living in the slums, alleys, and tenement houses, where filth abounds, it has been considered that high temperature acts by favoring the fermentation and decomposition of organic matter, thus loading the atmosphere with noisome vapors, which, in turn, depress the vitality of those inhaling them, or actually produce the disorders in question. Likewise, high temperature was supposed to act by causing fermentation and decomposition of milk and other foods ingested by infants. When these views were promulgated, fermentation and decomposition were considered to be purely chemical processes. At the present time, these facts are regarded as supporting the theory that micro-organisms play an important *rôle* in the causation of diarrhœas.

It has been a prevalent belief that a direct ratio exists between the range of the maximum daily temperature and the prevalence of diarrhœa, including cholera infantum. According to Seibert, of New York, this ratio exists with the minimum, rather than the maximum, daily range of temperature. This view appears paradoxical, but, upon examination, its truth becomes manifest. If a certain temperature be necessary for the development of an epidemic of summer diarrhœa, it is evident that a ratio will exist between the number of hours in the day during which the temperature is at or above this point, and the number of cases of diarrhœa; and that the epidemic will be greatest when the temperature is continuously above this point throughout the twenty-four hours. With a minimum daily temperature of at least 60° F., diarrhœas will largely prevail; and it is well known that this or a higher

temperature favors the activity of micro-organisms. Thus, from whatever standpoint the subject is viewed, the agency of high temperature in the production of diarrhœa seems to be that of affording one of the conditions favorable to the development of germs. Perhaps we may instance, as an exception, the depressed tone of the nerve-centres and tissues, brought about by high heat, which would itself act as a predisposing cause of diarrhœal or other disease.

The drift of opinion, recently, has been strongly toward the view that micro-organisms sustain a direct etiological relation to the summer diarrhœas of infants. The differences in the chemical composition of artificial foods and woman's milk, together with the relative indigestibility of the casein of cow's milk, have been considered the correct explanation of the greater liability to diarrhœa of artificially-fed infants. Unfortunately this view, which may be called the chemical theory, does not explain why artificial food agrees with infants in winter, and yet causes diarrhœa in summer. The researches of Escherich, Uffelmann, and Forster go far to show that our views as to the relative indigestibility of the casein from cow's milk have been exaggerated. However, we are not prepared to go so far as Escherich, who claims that cow's milk is not more difficult of digestion in the normally-developed infant than woman's milk. Still, these investigations, and the fact that artificial food agrees with infants in winter, and yet causes diarrhœa in summer, show that the cause of summer diarrhœas is to be sought elsewhere than in the chemical composition of the food. Clinical observation has shown that insanitary surroundings, artificial feeding, and excessive heat act in unison in the production of summer diarrhœa. The advocates of the germ theory claim that these facts receive their best explanation in the action of micro-organisms of fermentation, putrefaction, and those causing the development of ptomaines, and point out that the conditions named are those which favor a rapid multiplication of low forms of life.

We by no means believe that all diarrhœas in infants are caused by germs; but we feel convinced that efforts to provide infants with food and drink free from pathogenic and non-pathogenic organisms will result in greatly lessening the mortality of infants from diarrhœa.

EDITORIAL LABORS.

When the heats of summer fill the air, the Editor feels the oppression with his fellow-men, and is sometimes tempted to relax the diligence with which he performs his labors during the more genial or stimulating seasons of the year. This is when he is apt to put old society reports, or well-preserved clinical lectures, or stale abstracts before his readers, in the hope that they will be too conscious of the effect of the heat to attribute their weariness to what they are reading; while even the editorial columns exhibit languor, and look thin and lean, and other symptoms of summer-complaint appear in them.

These reflections have arisen in our mind while turning over the leaves of some of our contemporaries, and we have so much appreciated the hardship of having to work when everyone wishes to take his ease, that we have felt a sincere sympathy for our fellow-workers.

But here comes along a contemporary whose editor seems to have one side which does not feel the heat. As we came at him in the editorial pages, his aspect seemed meagre enough to justify a fear that marasmus was impending; but, when we turned to those pages devoted to cultivating the favor of his advertisers, all was hearty and jolly. Here was no apathy, no dulness. Our keenest solicitude was excited when we found less than two columns of editorial devoted to his readers; but we thought he might pull through when we found more than five columns testifying to the interest he takes in cultivating his advertisers! These

manifestations of unilateral vitality excited our interest to such an extent that we studied his case systematically, and we discovered that, however cataleptic he appeared on the side turned toward his readers, there was no mistaking the functional activity of the side presented to his advertising patrons. So far as we went, not a single one of these lacked evidences of his consciousness and power of recognition. Hardly an instrument was advertised, but he had used it with success; and hardly a remedy, but he knew from experience that it was of great value. Seriously or with flashing wit, he bestowed upon each a puff, and he even intimated that he meant to use a number of them on his own proper person! How deceptive, we thought, are appearances; here is at least half a cerebrum which no summer heat can dull, and half a mortal frame which no weariness can exhaust. And think of the results of even such one-sided cerebration! An editor like this must surely be regarded as a model by the advertisers, and it may indeed be that those who subscribe for his journal will forget the aridity of the part ostensibly devoted to them, while they browse about in the advertising-pages with a relish which comes of getting what one did not bargain for. Suppose some of them are led to appropriate a too varied diet, and afterward feel some regret—what of that? Will they thereafter eschew such tempting fare? Or can it be that this editor knows his readers' tastes, and has no fear that they will object to being tempted so and so misled?

Are those editors, after all, wrong, who take the work of editing seriously, and strive constantly to give their pages scientific value, letting the advertisers take care of themselves? Shall those who use their best efforts to elevate the tone of medical journalism prove to be less wise in their generation than those who introduce or cultivate the arts of the auctioneer?

Time will tell! but the medical men and women of this country will be responsible for the result. They will get what they really want. If they wish solid scientific work, they will get it; if they want ill-disguised advertising-mediums, they can get all they want even now; and, with such examples before us, we need not fear that the supply will run out.

PILOCARPINE.

Jaborandi and its principal alkaloid, pilocarpine, although comparatively new remedies, have come into extensive use. Perhaps pilocarpine is most relied upon in the treatment of uræmia and uræmic convulsions. It has been equally lauded in the treatment of puerperal eclampsia of supposed renal origin.

Our object in calling attention to the drug is to emphasize a certain danger which may result from its use. Most systematic writers on materia medica mention that it causes an increase of the bronchial secretion; but the subject is cursorily treated, and little stress is laid upon the fact that this secretion may become greatly augmented and cause a dangerous bronchorrhœa. Unfortunately, this fact is only too well known to clinicians. In a case of puerperal convulsions in a primipara, which occurred recently in this city, there was complete and persistent anuria. After the failure of various other measures of treatment, one-twelfth grain muriate of pilocarpine was injected hypodermically. The secretion of sweat was scarcely at all increased, but, within a few minutes, profuse bronchial and salivary secretion began and continued until the patient died. Two somewhat similar cases have come to our knowledge. One was a case of uræmic convulsions in a man. One-twelfth grain muriate of pilocarpine was injected hypodermically, with the result that within a few minutes profuse bronchorrhœa was induced, which lasted until the patient's death. The other was a case of atropia-poisoning. The patient had been treated in the usual way, but without special good

effects. The same amount of pilocarpine was injected as in the other cases, with the same result. It is not urged that pilocarpine was the cause of death in any of these cases, for, so far as human judgment could tell, they were fatal cases; but the bronchorrhœa induced by the pilocarpine certainly hastened the fatal termination. It must be remembered that only one-twelfth grain of pilocarpine was used in each of the cases, while it is common to inject one-eighth or even one-fourth grain. In view of this well-recognized danger, we think that pilocarpine should be used with caution, and that the initial dose for hypodermic administration should not exceed one-sixteenth grain. Should bronchorrhœa be induced, the best antidote is atropia.

THE FAMILY DOCTOR SOCIETY.

It is reported that a society bearing this name is being organized in Philadelphia, its object being to enable persons of limited means to secure medical attendance at a very low price; indeed, it is stated that the payment into its treasury of fifty cents a month will entitle a whole family to the services of a physician. This society seems to be organized somewhat on the basis of similar societies in London, which have been the occasion of considerable difficulty between the struggling members of the medical profession there and those who were more firmly established. It has been repeatedly asserted that these societies are simply used as means of advertising the medical men who give their services through them, and that, on the pretence of supplying medical services at a price much below what it is generally believed such services could be honorably rendered for, the medical officers of these societies manage to secure to themselves a variety of extra charges and perquisites, which compensate them for their trouble. Of course, it is possible that a society could be organized to furnish medical services to the worthy and self-respecting poor at a moderate figure, and that it could be conducted upon thoroughly sensible and truly charitable principles; but we seriously doubt that this result has ever been actually attained, and are inclined to share the opinion of those who look upon efforts ostensibly made to secure this object, with a good deal of suspicion, and fear that they will do more to degrade the standing of the medical profession than they will to improve the condition of the poor.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

LECTURES ON DISEASES OF THE HEART, DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK. By ALONZO CLARK, M.D., LL.D., Emeritus Professor of the Principles and Practice of Medicine, etc. 8vo, pp. 251. New York: E. B. Treat, 1887. Price, $2.75.

It is four years since these lectures were published by the late Dr. Clark, and it is a good thing to have them republished in the series of "Treat's Medical Classics," with the hope of securing for them a wider circulation. It is hardly necessary to say anything of their scientific value; for the reputation of the author as an able diagnostician and successful practitioner is familiar to most American readers. It may be said, however, that his lectures are written in an interesting and attractive style, and that, while they have not the conciseness looked for in systematic treatises, they have the charm of easy and colloquial expression, which is one of the best features of good clinical lectures.

One attractive thing in this book is the fact that it is quite American. The writings of foreign authors are cited, it is true; but most of the references are to the work of physicians of our own country, and full justice is done them.

THE PATHOLOGY, DIAGNOSIS, AND TREATMENT OF THE DISEASES OF WOMEN. By GRAILY HEWITT, M.D., F.R.C.P., Professor of Midwifery and Diseases of Women, University College, etc., New American, from the fourth London, edition, with 236 illustrations. Edited, with notes and additions, by H. MARION-SIMS, M.D., New York. Three volumes, 8vo. New York: E. B. Treat, 1887. Price, each volume, $2.75.

This book belongs to a class of which we have never entertained a very high opinion. They are published apparently chiefly to secure a wide distribution and to carry off a great many volumes on the strength of the names of the authors, without a due regard for the demands of good writing or good book-making. The authors of the volumes before us are well known—at least one of them is; but we do not think the reputation of either will be much enhanced by this production. It is true that it contains a good deal which is interesting and instructive; but in the whole work there is too much of an appearance of an effort, on the part of the authors as well as of the publishers, to make a big book of it, and to work the

subject over as much as possible. This fact makes a bad impression on us; and this is heightened by the wretched manner in which the book is illustrated and printed On the whole, we think our readers can spend $8.25 to better advantage than in buying these three volumes.

INTUBATION OF THE LARYNX. By F. E. Waxham, M.D., Professor of Otology, Rhinology, and Laryngology, College of Physicians and Surgeons of Chicago, etc. 8vo, pp 110. Chicago, Ill.: Charles Truax, 1888. Price, $1.25.

This handsome book contains a full and clear description of the operation of intubation, and a good outline of its history. The description is accompanied with illustrations which leave nothing to be desired. To carry out the operation requires, of course, a certain degree of manual dexterity; but any physician who has the necessary skill in using his hands ought to be able to do intubation after carefully studying Dr. Waxham's instructions.

As is well known, Dr. Waxham has preached and advocated intubation in the treatment of membranous laryngitis even more ardently than Dr. O'Dwyer, who introduced the method. He thinks it preferable to tracheotomy, and seems to be justified in doing so by his personal experience and the statistics which he has collected. His argument is interesting and very persuasive, and we can heartily recommend his book to our readers, and congratulate him upon its admirable character, and his publisher upon the handsome way in which he has brought it out.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

Inguino-properitoneal Hernia. By Wm. Stone Torrey, M.D., Brooklyn, N. Y. From the *Annals of Surgery*, March, 1888. 10 pages.

Hernia Inguino-properitonealis, with an Account of a Case. By Charles W. Dulles, M.D., Philadelphia. From the *Medical News*, January 22, 1887.

The Neural and Psycho-neural Factor in Gynæciac Disease. By C. H. Hughes, M.D., St. Louis. From *The Alienist and Neurologist*, April, 1888. 16 pages.

On the Nomenclature and Classification of Diseases of the Skin. By L. Duncan Bulkley, A.M., M.D., New York. From the *Archives of Dermatology*, October, 1881.

Hysterorrhaphy. By Howard A. Kelly, M.D., Philadelphia. From the *Amer. Jour. of the Med. Sciences*, May, 1888.

Papillomatous Cystic Tumor of Ovary, with Hernial Pouch Developed in the Cicatrix of the Abdominal Wound from a Former Ovariotomy. By L. H. Laidley, M.D., St. Louis. From the *Journal of the Amer. Med. Association*, April 14, 1888.

The Intra-Uterine Stem in the Treatment of Flexions. By A. Reeves Jackson, A.M., M.D., Chicago. From the *Gynecological Transactions*, 1887.

The Heat-Centres of the Cortex Cerebri and Pons Varolii. By Isaac Ott, M.D., Easton, Pa. From the *Journal of Nervous and Mental Disease*, February, 1888. 20 pages.

—Dr. Torrey gives an account of a case of properitoneal hernia in which he operated by opening the hernial sac over the inguinal canal and over the abdominal swelling. His patient seemed to be in a fair way to recover, when, on the third day, he got up on the chamber to have a stool, and died in a few hours, of heart-failure. The case is an interesting one, and Dr. Torrey's paper deserves attention, especially as the writings on the subject in the English language are very few. In this country, only three operations for properitoneal hernia have been reported—one by Dr. Dulles, of Philadelphia; one by Dr. Hartley, of New York; and this one by Dr. Torrey. Dr. Dulles's patient died from unrelieved strangulation, Dr. Hartley's patient recovered, and Dr. Torrey's case ended in death, from no fault of the operator. The experience of these operators seems to justify the opinion that laparotomy is to be preferred to herniotomy in the treatment of cases of this sort; but this cannot be established until a larger number of cases have been reported, and especially a larger number of laparotomies.

—Our object in calling attention to the paper on inguino-properitoneal hernia by the editor of the Reporter, in connection with that by Dr. Torrey, is to inform our readers that a copy of it will be sent to anyone who wishes, on application. It was written with the hope of diffusing information in regard to a form of hernia which is by no means very uncommon, but which is rarely recognized; and we trust that this allusion to it will not be regarded as improper, in view of the writer's belief that unrecognized cases of properitoneal hernia usually terminate fatally, while those which are recognized before operation are quite amenable to surgical treatment.

—Dr. Hughes's pamphlet contains a paper read at the Ninth International Medical Congress, in which he argues for the importance of properly estimating the influence of the nervous system in producing morbid symptoms or morbid conditions in the pelvic organs of women. Beside this, it contains a timely appeal to physicians to remember that all diseased states, however local apparently, should be studied with a due appreciation of the general state of the patient, and of what may be going on in remote parts of the organism. As a neurologist discussing a gynecological subject, Dr. Hughes says many things which might be pondered over with advantage by medical men following both of these specialties, as well as by all practicing physicians.

—This somewhat belated pamphlet of Dr. Bulkley's comes to our table for notice at a time when even the name of the publication in which it first appeared has given place to another. Still, the pamphlet is interesting, as marking one of the steps by which dermatology has come to have one of the most comprehensive and exact nomenclatures in all the round of the medical specialties.

—Dr. Kelly, in this pamphlet, advocates the practice of stitching the fundus of the uterus to the abdominal wall in certain cases of intractable retroversion or retroflexion, and fortifies his position with the histories of a number of cases operated on by European surgeons, and reference to an operation of his own, the details of which he promises to give in a later publication. He also describes the method of operating, and illustrates it with three good wood-cuts.

—Dr. Laidley's case is a very interesting one, and illustrates a number of important points in connection with abdominal surgery. In some regards, it teaches

what should be done, and in some it indicates what ought not to be done. As an operation, Dr. Laidley's work was entirely successful, as he freed his patient from an ovarian tumor, healed a fistula, and cured an abdominal hernia.

—Dr. Jackson, in this paper, proposes a method of using stem pessaries which has many theoretical advantages, and which seems to have proved both safe and efficient in his hands. It consists, essentially, in using flexible rubber stem—not a hard vulcanite one—beginning with a small size and gradually advancing to larger ones, and only after a period of some months coming to a full-sized and inflexible instrument. The good results he has observed after employing this method lead him to oppose the opinions of those gynecologists who regard the stem pessary as ineffectual and unsafe. The latter may, however, find ground for a rejoinder in Dr. Jackson's statement that in fifty-two of the sixty-seven cases he reports, the patients had anteflexion, as against only fifteen with retroflexion.

—Dr. Ott's paper contains another of those carefully-prepared contributions to our knowledge of experimental pathology—and indirectly to physiology—for which he is already so well known. By injuring or removing a portion of the brain in cats, at the points regarded as presiding over heat-production, he found that a point at the juncture of the supra-Sylvian and post-Sylvian fissures had the highest thermic value, and injury of other parts of the brain, with the exception of the cruciate centres, had but little effect on the temperature. To understand the value of these experiments demands a careful study of Dr. Ott's paper, and we can do no more here than to call our readers' attention to it.

CORRESPONDENCE.

Strongulus Gigas.

To the Editor.

Sir: With your permission, I will report a case of "Strongulus Gigas" which came under my observation last fall. The subject is interesting because of the extreme rarity of cases and our lack of knowledge concerning this parasite. Even persons recognized as authority on diseases of the kidney seem never to have heard of the formation of worms within its substance.

The patient, Mr. R. E. Adams, 73 years old, had been gradually failing in health for one year. His symptoms were, for the most part, those of dyspepsia, with nothing pointing directly to renal trouble except some vague pains in the back. In September, 1887, he made a business trip to Nebraska, and while there, at the residence of his son, was seized with a severe attack of renal colic. No physician was called, but by the use of domestic remedies the attack subsided, and in a few days he passed from the bladder a half-dozen worms. He returned home, and, on October 21, came to consult me. He complained only of extreme weakness and fatigue on the least exertion. His appetite was poor, sleep moderately good; he did not feel sick. When he spoke of having passed worms, I requested that should any more make their appearance he would allow me to see them. In a few days he brought one to my office, the last and only one he passed after coming home. This one was about three inches in length, two lines in diameter, bearing some resemblance to the common earth-worm. He said the others were both longer and thicker, which statement was endorsed by his son, who had seen them. His urine I found to be highly albuminous. P. W. Lewellen, M.D., of Clarinda, President of our State Board of Health, very kindly made a microscopic examination of it for me, and reported that he found "no tube casts but some hyaline casts." After a few weeks' treatment, I frankly told him I could not do anything but palliate his trouble. He decided to try the virtues of the mineral springs at Burlington Junction, Mo. In about three weeks he returned home, a great deal weaker than he left. About this time his feet and hands began to swell, and this was followed by a general dropsy.

During all this time I was trying to learn something more about these parasites, but could find scarcely anything concerning them. Physicians with whom I would talk were as ignorant as myself, and some would even stare in surprise at the mention of it. I wrote to a friend, M. W. White, M.D., who was attending Bellevue College, and had him interview some of the professors on the subject, and here are the answers: One thought they were sometimes formed in the pelvis of the kidney, but knew nothing of the cause or pathology. This expressed my own opinion. Another had seen one case in which worms were passed from the bladder, but at the autopsy it was found that the patient had had typhlitis and local peritonitis. There was also inflammation of the vermiform appendix, with perforation at its lower end, and adhesions to the bladder, with perforation of it. Not only worms but other solid matter was passed by the urethra. He said the kidneys were not affected at all, and gave it as his opinion that worms of the size I mentioned were never formed in the kidney or urinary organs. He thought there must be some communication between the urinary and intestinal tracts. A third professor had never seen a case, but thought there must be adhesions and perforations of some portion of the urinary tract. Well, my patient died December 29, and, the

following day, assisted by Dr. W. T. Chambers, of Blanchard, Iowa, I made an autopsy.

We found the right kidney enlarged, weighing two and a half pounds, not a particle of healthy or normal tissue about it. In external appearance, it resembled a fatty kidney. We found no worms either in the kidney, ureter, or bladder; but, on section, we found unmistakable evidence of their habitation. About one-fourth the entire mass, including the pelvis and infundibula, presented the appearance of being eaten by worms; looked like a mass of dry curds. The left kidney was also affected in its superior border, and would probably have weighed one-half pound; but there were no indications that it had ever been invaded by the parasites. There were two or three points of similar deposit in the liver, but they were small. The heart was flabby and showed considerable muscular degeneration. The other viscera were in their normal condition. There was no evidence of any peritonitis, typhlitis, or any other "itis." Bladder and ureters were in a healthy condition, and *no abnormal adhesions anywhere* There was no communication between the alimentary and urinary tracts; consequently the worms came direct from the kidney. Through Dr. Lewellen, I sent a portion of the kidney to a Chicago pathologist for examination, but he was away from home at the time, and the examination was never made.

Hoping by this report to throw a small ray of light on a very dark subject, I am

Yours truly, M. R. George, M.D.

College Springs, Iowa,
June 20, 1888.

Wounds of the Palmar Arch.

To the Editor.

Sir: Having seen some recent articles in the Reporter in regard to wounds of the palmar arch, I thought it might be of interest to send the report of a recent case which came under my treatment. The patient was about to take the cap off a brass shot-gun shell, which had been snapped, but had missed fire, when it exploded, the sharp edges of the shell lacerating the hand severely, cutting the superficial palmar arch in such a manner as to cause profuse bleeding.

The treatment consisted in first ascertaining if there were any foreign substances lodged in the wound, then adjusting the parts, and applying subsulphate of iron on a wad of antiseptic cotton held in place with a bandage. Over this were placed two letter-bands, which made sufficient pressure to control the hemorrhage. I was sent for in a few hours, and found the patient complaining of a good deal of pain in the hand and arm. One letter-band was removed and the hand elevated. The suffering was then greatly relieved. On the second day, the bandages were removed, and, on the third day, the cotton was soaked loose, when there was a profuse sanguineous discharge, which gave great relief. The wound was then dressed with lanoline ointment, with moderate pressure. After this, there was rapid recovery.

I forgot to say that, in this case, there was a backward dislocation of the third phalanx of the middle finger.

Yours truly,

J. M. G. Beard, M.D.

Ambia, Ind.,
Aug. 4, 1888.

Hydrofluoric Acid in Phthisis.

To the Editor.

Sir: You would do me a great favor by instructing me how to use hydrofluoric acid in the treatment of phthisis, and where I can get the necessary apparatus for using it.

Yours truly,

Wm. Hoffbauer, M.D.

Guttenberg, Iowa,
Aug. 8, 1888.

[As our correspondent will see, by referring to the Note and Comment in the Reporter, May 19, 1888, p. 653, the method of using the acid is not as simple as one could wish. The atmosphere of a chamber, tent, or cabinet is saturated with the vapor of hydrofluoric acid, generated by passing a current of air through a solution of 9½ ounces of distilled water and ¾ of an ounce of hydrofluoric acid. This solution is contained in a tank made of gutta-percha. To obtain the beneficial results of these inhalations, the patient should sit for one hour a day in the atmosphere generated as above described. Doubtless any receptacle which would not be acted upon by the acid would answer as well as one of gutta-percha. Editor of Reporter.]

Carrying Nitro-glycerine.

To the Editor.

Sir: Is there any danger from explosion attendant upon carrying a one per cent. solution of nitro-glycerine in the pocket in traveling over the country, as I have to do in my practice? And is there any danger in keeping it on the shelf in the office, or in handling and dispensing it? And ought patients and others to be cautious when doing so? Will you please answer, if convenient, in Reporter?

I have only lately commenced using it

in my practice, having been deterred from doing so much earlier on account of the explosive character of the article, at least when not in dilute solution. From my limited experience with it so far, I have no doubt of its greatly beneficial effects in morbid states in which there is retarded circulation or local blood-stasis, as well as in certain forms of neurotic affections. Prof. H. C. Wood, in his last edition of U. S. Dispensatory, is not very explicit in regard to the non-explosive character of an alcoholic solution of nitro-glycerine, though he says that it is *claimed* that it is not explosive. Hence, I address myself to you as above, to obtain the information necessary to guard against danger, if there is any, from the source indicated.

Yours truly,

Halifax, Pa., H. W. Bishoff.
August 8, 1888.

[An alcoholic solution of nitro-glycerine, of a strength of ten per cent., is absolutely free from danger so far as explosion is concerned, and so, of course, must any weaker solution be. Editor of Reporter.]

Notes and Comments.

Treatment of the After-birth in Normal Labors.

Credé, of Leipzig, writes in the *Archiv für Gynäkologie*, Band 32, Heft 1, in answer to a discussion upon his method of treating the third stage of labor, which occurred at the Wiesbaden Congress of last year, and in which varied criticisms and modifications were suggested. He reminds his readers that, when he first advocated the method which commonly bears his name, there were but two procedures in vogue: that which consisted in removing the placenta with the hand, or an instrument introduced from without, and the expectant plan, which relied entirely upon nature. He comments upon the misstatements of his method which have been made, and considers the term "external method" as its most appropriate designation.

The most decided criticism made against Credé's exposition of his method is that he does not define clearly enough the time at which the placenta is to be delivered. He considers that the choice of the time for employing his treatment depends upon one of the three indications for terminating labor, which are as follows: terminating a dangerous condition already established; the prevention of accident; saving of time. Regarding the first, there can be no question that the patient must be rescued from her peril at once by bringing labor to a close. Regarding the second, Credé's experience has led him to believe that in the majority of normal labors, when the uterus contracts well and responds to massage promptly, that three or four after-pains suffice to expel the placenta in from fifteen to thirty minutes after the birth of the child. He does not, however, advise that labor be ended invariably in this time; he recognizes the fact that many circumstances may render the exercise of a more expectant course of action necessary. The saving of time and suffering he thinks well worthy of serious consideration, from the interests of attendants and patient alike, especially since the method of treatment advised exposes the patient to no added danger. He replies to the objection that greater loss of blood results from his treatment by stating that the loss of blood in a labor depends upon so many factors that it would be difficult to assert that any one is solely the cause; he is positive that the loss is not increased, but in his experience diminished, by his delivery of the placenta.

He also thinks that the retention of chorion and decidua is not more frequent among patients so treated; it occurs with about equal frequency, he says, with various methods of treating the third stage of labor. In four and one-fourth years, he has treated 4969 patients in the Leipzig clinic without a case of retention, death, or serious complications which could be ascribed to this treatment. The cause of puerperal accidents he believes to be the meddlesome practice of the accoucheur; for fragments of placenta and membranes, when left to nature and without infection conveyed by instruments, Credé believes to be innocuous. Auto-infection in such a case he considers impossible; the infecting material must come from without, and be absorbed by a recent wound, or an old wound recently freshened.

To the criticism that uterine massage, or "rubbing of the uterus," is unnecessary and dangerous, Credé replies that he does not advocate violence, but gentle patient massage and stroking of the uterus, which, when done by a practiced hand, cannot do harm. This method is not difficult to acquire, but is not a trivial procedure, or one to be performed without care and skill. A student should learn first to stroke gently the entire anterior surface of the uterus, then to straighten the uterus, and place it so that its direction (or axis) corresponds with that

of the sacrum and coccyx, and, finally, he should add pressure exerted upon the uterus. The last is intermitted during uterine contractions. It is usual in patients so treated to find the placenta lying in the vagina after a short time.

A substitute proposed for this treatment is pressure by the abdominal muscles, which evidently is poor reliance in a condition in which the tissues have been distended and weakened, and where the mother's strength is nearly spent by her labor. To the proposals to rub only the inferior segment of the uterus, and also to push it upward above the supposed site of the placenta, Credé replies that the most efficient muscle of the uterus is in the superior and not in the inferior segment, and hence the part most powerful to contract should be stimulated: if the uterus be strongly pushed up immediately after delivery, a laceration of the cervix may be made larger; it is unnecessary strongly to raise the uterus, for stimulation of any portion of the uterine muscle will result in the contraction of the whole. He does not believe that the placenta is separated by the formation of a blood-clot between the placenta and the uterine wall, but believes that the uterus expels the placenta by its contractions, as it does the child.

Credé feels justified in concluding that the method which he originated is correct in principle, and in practice is without objection. He has no reason as yet to alter his method; the improvements suggested by others are already possessed by his treatment, or they are unimportant. He believes that no occasion has been shown for adopting any of the modifications proposed.—*American Journal of the Medical Sciences*, June, 1888.

Round Perforating Ulcer of the Duodenum.

Dr. W. W. Johnston, in an article on Round Perforating Ulcer of the Duodenum, in the *American Journal of the Med. Sciences*, July, 1888, gives the following points in the differential diagnosis between gastric ulcer and duodenal ulcer:

GASTRIC ULCER.

1. Most common in women from twenty to thirty years of age.
2. Pain in epigastrium soon after eating.
3. Pain relieved by vomiting.
4. Vomiting of mucus, bile, and food—gastric indigestion.
5. Hæmatemesis common.
6. Hemorrhage from intestines rare.

DUODENAL ULCER.

1. Most common in men from thirty to forty years of age.
2. Pain in right hypochondrium two to four hours after eating.
3. Pain not relieved by vomiting.
4. Vomiting rare; no gastric indigestion.
5. Hæmatemesis rare.
6. Hemorrhage from intestines common.

One would be justified, he says, in making a diagnosis of duodenal ulcer if a man, otherwise in good health, between thirty and forty years of age, suffers with attacks of severe pain below the edge of the liver to the right of the median line, the pain coming on from two to four hours after eating, lasting for from one to four hours, and gradually lessening, to recur after the next meal, being most prolonged and most severe at night. Such a symptom, without gastric indigestion or the evidence of any organic lesion, pursuing a chronic course during a year or more, with remissions and exacerbations, being benefited by liquid diet and aggravated by indiscretions in diet, could reasonably be attributed to duodenal ulcer as a cause. This diagnosis would be confirmed by the occurrence of intestinal hemorrhage or by the sudden development of perforative peritonitis.

The Significance of Double Vision.

In the *St. Louis Med. and Surg. Journal*, July, 1888, Dr. A. D. Williams says that so long as the eyes move in harmony with each other we have single or natural vision. But let these harmonious movements be disarranged by excessive or deficient movement of either eye, double vision at once takes place. Diplopia, therefore, signifies that the eyes have ceased to harmonize perfectly in their movements. This results usually from defective action of one or more of the "motors" of the eyes, and consequently when we have double vision we must expect to find its cause in one or more of the recti muscles. The position of the images with respect to each other must determine which muscle is at fault. This is not always an easy task because of the complex nature of the associated movements of the eyes. It occasionally happens, though very rarely, that a person sees double with *one* eye. This can only occur from the defective sphericity of the cornea, congenital or acquired. In muscular diplopia, of course, the treatment must be directed to the correction of muscular action, from whatever cause it may arise.

Slag for Absorbing and Deodorizing Fecal Matter and Urine.

Amongst the many materials that have been suggested and used, from time to time, for the purpose of absorbing and deodorizing fecal matter, not one, perhaps, is so interesting to those engaged in sanitary science, says the *Lancet*, July 7, 1888, as the one whose properties were demonstrated at a meeting held in St. Stephen's Hall, Princes Street, Westminster, on Tuesday last, inasmuch as the material used—viz., common slag—has puzzled for a long time many a practical chemist and engineer to know to what purpose it may with profit be applied. We remember hearing, however, some months ago, of the application of crushed slag as a dressing in agriculture for heavy clayey soils. It is said to be extremely porous, rendering the soil more absorbent, and is also of value as a manure on account of the notable quantity of phosphoric acid it contains. This most important subject of dealing with the sewage of our towns has been so much discussed, and is so well worn, that to point out the advantages or disadvantages of the dry-earth system over that of the water-carriage system were superfluous. Suffice it to say, the inventors of this new material for the defecation of sewage-matter (Messrs. M'Gregor and M'Arthur, of Dundee) take for granted that the advantages of the former system, at least in many cases, are unquestionable. They further claim for it the following additional advantages: (1) the cheapness of the material, the cost being roughly estimated to be from one to two dollars per ton, including crushing and carriage; (2) its supply being practically inexhaustible; (3) its porous property, which, independent of (4) its manurial qualities, renders it valuable to clayey soil. Dr. Redwood gives the following analysis of the material after use:

	Per cent.
Fixed inorganic matter, after ignition	71.68
Insol. silicious matter	60.50
Lime	2.85
Phosphoric acid	2.31
Organic matter, with ammonia and water	28.32
Ammonia, ready formed	.08
Organic nitrogen	.13
Equal to ammonia	.15

A sample was exhibited which had been in use five weeks ago, in which we failed to detect the slightest smell. The method of using it is similar to that adopted in the other earth-closets. The pan is first charged with a certain quantity of the crushed slag, and, after use, another quantity is put in, the total quantity necessary, according to the inventor, being a third less than ordinary dry earth—that is to say, six persons would require one-third of a hundred-weight of defecating matter per week. These assertions are so strong that a careful trial of this method, and, indeed, of any new method which aims at the healthy as well as useful disposal of so great a nuisance, is well worthy the consideration of every sanitarian.

"Pharmaceutical Specialties" in Belgium.

The Liège Medico-Chirurgical Society has addressed a communication to the Belgian Minister of the Interior on the subject of a royal order referring to "pharmaceutical specialties," which was published in March, and which, though admirable as far as it goes, leaves, in the Society's opinion, considerable room for improvement. The order provides that pharmaceutical specialties must bear a label indicating the names of the substances comprised in them. The object of this is to prevent the pharmacist from selling medicines of the composition of which he is ignorant; but it does not apply to specialties sold directly to patients by the pharmacist when he has made them up himself. This regulation, the Liège Society suggests, should be extended so as to include the obligation to affix not only a qualitative but a quantitative label, and also to compel all pharmacists, even those who have themselves made up the specialties, to conform to the rule. It is also hoped by the Society that the Government will see its way to a considerable amount of restriction on the pharmaceutical advertisements in political journals. The Society remarks that pharmaceutical specialties intended for prescription by medical men ought certainly to indicate the dose of each component, for the prescriber's guidance. As to those intended for the indiscriminate use of the public, and which are supposed to cure nearly all diseases, the existence of these is objectionable; but, if they are allowed at all, the dosage should be clearly indicated. This might, perhaps, operate as a caution to a purchaser, as it would suggest a doubt as to whether the dose was a proper one for his particular case. The exemption from the regulation of the pharmacist who has himself made up the medicine would seem to encourage pharmacists to take upon themselves the functions of medical men, a *rôle* they are only too apt, as it is, to play. This exemption ought certainly to be abolished. —*Lancet*, July 7, 1888.

Dr. Atlee's First Ovariotomy.

We are informed that the patient upon whom Dr. John L. Atlee performed his first ovariotomy, in 1844, is still living. The operation was a double ovariotomy, and was the first of that character ever performed.

Dr. Ehler, of Lancaster, assisted at the operation, and he says that the patient occasionally visits him.

Use of Drainage-Tubes After Ovariotomy.

Dr. Charles E. Taft, late House Surgeon to the Woman's Hospital, New York, in a communication in the *N. Y. Med. Journal*, July 14, 1888, expresses his opinion regarding the use of drainage-tubes after ovariotomy, in the following propositions:

"1. A glass drainage-tube of rather small diameter and thick walls should be used in preference to all others.

"2. A drainage-tube should be inserted when in doubt and when any of the causes for its use are present.

"3. A tube which is not perforated along the sides answers every purpose.

"4. The contents of the tube should be removed at very frequent intervals—every half-hour to three hours.

"5. One of the greatest uses of the tube is in the early demonstration of hemorrhage.

"6. A tube should be removed just as soon as the discharge becomes clear serum.

"7. When a drainage-tube is left in too long, a sinus remains which it is frequently impossible to close, and there is an increased liability to hernia.

"8. In draining a sac, a large and free opening made at the time of operation seems preferable to sewing the sac-walls closely around a drainage-tube."

A Good Reply.

A Detroit attorney thought he made a strong point when he asked an expert witness in court, recently, if there was anything injurious to health in the water used by the defendant to adulterate milk. The proper answer to such a question, says the *Pharmaceutical Era*, July, 1888, would be a most emphatic "yes, as injurious to health as nitrogen substituted for atmospheric air to breathe; thousands of children in our cities die annually from feeding them water instead of milk." In truth, no one but a lawyer would think it smart to ask such a question, and there are few juries who have not intelligence enough to see how weak a cause must be which requires a resort to such transparent trickery for its defense.

Mississippi Valley Medical Association.

The Mississippi Valley Medical Association meets at St. Louis, September 11, 12, and 13 next. The first day will be given to the discussion of abdominal surgery; the second, to infant-feeding and some obstetric subject; the third will be taken up with volunteer papers and some neurological subject. The Society cordially invites all members of the profession to be present. Arrangements are being made for reduced rates, in regard to which, communications may be addressed to Dr. J. Lucius Gray, Secretary.

This Association always has good meetings, and the coming one gives promise of being like the former ones. Those who have a chance to go should be sure to do so.

NEWS.

—Franz Zuppel, of Laurel Run, Pa., swallowed two ounces of chloroform liniment, while drunk, July 30, and died in two hours.

—Telegraphic reports from Jacksonville up to August 18 indicate that the yellow fever there is under control, and that the confidence of the people is being restored.

—The Landtag of Finland has sanctioned a law which imposes a fine on persons convicted of prostitution. Forty marks (about $8) for the man, and half as much for the woman.

—The State Boards of Health of Louisiana and Mississippi, and the authorities of Columbus, Georgia, have declared quarantine against the towns in Florida infected with yellow fever.

—The City Council of Atlanta, Georgia, has added $5000 to the fund of the Board of Health, in order to keep the city in a healthy condition. There are many Jacksonville refugees in the city.

—One case of small-pox has developed in the State prison at Trenton, N. J. Vaccination of the 900 convicts was begun August 13, and a general fumigation has been performed. All work in the shops is suspended.

—In a note to the Academy of Sciences of Paris, July 23, 1888, MM. Teissier and Germain Roque stated that they had been investigating the toxicity of albuminous urine by injecting it into the auricular vein of the rabbit. The results obtained are not given.

—Dr. Caroline S. Rodgers, of Rochester, N. Y., has been appointed examining physician to the department for women of the State Industrial School. This is said to be the first time the State has made an appointment of this kind. Dr. Rodgers is well known in Rochester society.

—The Health Officer of Philadelphia, in a report to the Board of Health, August 16, stated that during the previous week 8 cases of small-pox, 10 of diphtheria, 173 of typhoid fever, and 13 of scarlet fever had been reported; while there were 2 deaths from small-pox, 28 from typhoid fever, 2 from diphtheria, and 4 from scarlet fever.

—The *Atlanta Med. and Surg. Journal*, August, 1888, says that, at a recent meeting of the Atlanta Society of Medicine, one of the members offered a resolution pledging the members to boycott all drug-stores where counter-prescribing was indulged in. The resolution was not passed, because the members believed the boycott would be universal, and therefore impracticable.

—Mail-matter from Florida has been concentrated at a fumigation-station near Waycross, Georgia, and will be thoroughly fumigated and forwarded to its destination. All mail originating outside of Florida is sent to its destination in that State by whatever route remains open by day, and by which it can be delivered without passing through infected or quarantined districts.

—The *Lancet*, August 4, 1888, says that a case of partial sloughing of the cornea is reported by Dr. Kuritzin, due to exposure for nine hours on a Russian steppe, driving against a snow-storm. Both eyes were similarly affected, somewhat deep ulcers having formed, in shape and position corresponding to the openings between the eyelids. The other parts of the eyes were scarcely affected at all. The patient, who had never previously suffered from any affection of the eyes, made a good recovery.

—The *Boston Med. and Surg. Journal*, August 9, 1888, says Judge Aldrich, of the Superior Court, granted an injunction, August 2, restraining Dr. Frank L. Weir from practicing as a physician in Taunton, Mass., or within ten miles of Taunton Green, for five years, under an agreement made with the plaintiff in this case in July, 1887. The plaintiff, who went abroad, leaving his patients in the care of the defendant, alleged that, in violation of the contract, the defendant had opened an office in Taunton.

HUMOR.

HARD PRESSED.—"If anybody was ever more pressed for time than I am, I'd like to see him." "There is such a fellow on exhibition at the museum." "Who is he?" "An Egyptian mummy."—*Life.*

A THINNER KIND.—"I tell you what it is, Bovine, the milk you serve is the thinnest kind I ever saw." "Well," said Bovine, "if it is thinner than the milk of human kindness, I'll give up the business." Bovine is still in the business.—*Harper's Bazar.*

"WELL, JAMES," said the chiropodist, "we must keep up with the times. Look at this new sign." "Capital!" exclaimed the assistant. "That will surely catch the public." Then he went out and tacked up a sign that read: "Corns Removed While You Wait."—*Detroit Free Press.*

EDWARD: "I suppose you learned at Vassar the inexplicable difference between the anatomy of a dog and that of other animals?" Sophia (who has just been graduated with an M.D.): "Why—er—no, that I remember. What is it?" Edward: "His lungs are the seat of his pants."—*Life.*

DRUGGIST: "Yes, I want a prescription-clerk. Have you a diploma?" Applicant: "Not exactly, sir, bu—" Druggist: "Can you run a soda-fountain?" Applicant: "Not very well, sir, but I can learn." Druggist: "No, I guess you won't do. I might let you practice putting up prescriptions, but I can't afford to risk an inexperienced hand at the soda-fountain."

ASTONISHED INDEED.—The Editor's Wife: "Charles, I have just read that M. Gregoki, the editor of the *Athens Gazette*, writes three columns of editorials every day of his life. Isn't that astonishing?" The Editor: "Not at all, my love. I frequently write four columns a day." The Editor's Wife: "Ah, yes, Charles, but M. Gregoki writes in Greek. Think how difficult that must be!"—*Harper's Bazar.*

A WEST END THIEF, who was arrested Monday night for drunkenness, said on Tuesday that it was a downright shame. "For," said he, "I am a thief, and a good one, and it will hurt my reputation among my pals to be arrested for simply being drunk. If it was for robbery, or something like that, I wouldn't care, but I don't want to be arrested for drunkenness."—*Boston Journal.*

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

Our New Lens Front, or Magnifying **Clinical Thermometers, with Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

Clinical Lecture.

VESICAL FISTULA; FIBROID OF UTERUS; Etc.

BY JAMES B. HUNTER, M.D.,
PROFESSOR OF GYNECOLOGY IN THE NEW YORK POLYCLINIC, AND SURGEON TO THE WOMAN'S HOSPITAL.

Case of Vesical Fistula.

The patient before you is 53 years of age, and more than twenty years ago was a patient in the Woman's Hospital. She was operated upon several times by Dr. Emmet for the cure of a large vesico-vaginal fistula. A great part of the base of the bladder had sloughed away. The cause of the fistula was a severe labor, lasting over twenty-four hours, and ended by the use of forceps. I myself was house-surgeon in the Woman's Hospital when she entered, and well remember her condition, which was one of the most deplorable I have ever seen. She was ultimately cured of all but a small cervico-vesical fistula, which remained for many years, but has now ceased to occasion her any trouble. Her complaint now is of slight prolapse of the anterior vaginal wall, and a feeling of pressure on the bladder. When standing or walking for a long time, she has slight incontinence due to cicatricial contraction laterally, in consequence of which the lower portion of the urethra is retracted and its proper functions interfered with. She has not much pain, and ordinarily there is no involuntary escape of urine. But the capacity of the bladder is small, and she has to empty it at least every three hours. She is entirely relieved of nearly all her symptoms by the introduction into the vagina of a small glass ball, which presses the neck of the bladder somewhat forward.

The case is a very interesting one, as showing what extensive loss of the vagina may be repaired. The patient has been actively engaged most of the time on foot during all the years that have elapsed since she left the hospital.

Fibroid of the Uterus.

This patient is thirty-eight years of age; has had one child and one miscarriage. Seven years ago she began to complain of pain in the back and menorrhagia. On examination we find the body of the uterus apparently about four times its normal size, and we find that the sound passes four and one-half inches, and to the left side. The solidity of the mass is evident to the touch, and it is also evidently continuous with the uterus.

There are several ways of treating these cases; we are guided largely by the symptoms, by the size of the tumor, and by the age of the patient. This woman has not much pain, and complains chiefly of the excessive loss of blood at every period. We naturally suspect that this elongated uterine canal contains fungoids, and we satisfy ourselves of the fact by passing the blunt curette. Now, if we carefully scrape out all these granulations, and apply strong tincture of iodine to the surface, the hemorrhage will be arrested, and the patient will be relieved for three or four, or perhaps for six, months, though of course the condition is not otherwise benefited. If the woman were ten years younger, and the tumor were growing rapidly, more heroic treatment would be demanded. But if she can hold out a little longer, until the menopause, the

tumor will cease to grow, and may perhaps diminish in size. It is worthy of note, however, in this phase of expectant treatment, that the menopause is often delayed for several years on account of fibroid tumors. Medicines have very little effect upon these growths; but, in some forms of tumor, where the uterine tissue can act upon the neoplasm, the use of ergot tends to check the hemorrhage. The application of iron or other styptics is of no use whatever. The internal administration of quinine and of iron tends to increase the flow.

In case of a younger woman having a similar growth to the one before you, we have several means at our disposal for relief and cure. One to which much attention is now being directed is the use of a powerful galvanic current, after the plan of Apostoli, of Paris, who, when he was in this country, kindly operated upon a case for me in order to demonstrate his method. He passes one electrode of platinum into the uterus, and for the other electrode covers the entire abdomen with a mass of wet clay, much like a flax-seed poultice. Operating in this way, he is able to apply a current ten times more powerful than had formerly been employed for this purpose. This treatment, continued for ten or fifteen minutes, is not painful to the patient, and, if followed by no reaction, it is repeated two or three times a week. The result is a change in the nutrition of the tumor, and a partial arrest of its blood-supply. We have not yet used the method often enough in this country to speak of it with much confidence, but it is certainly worthy of trial. It is entirely different, you will observe, from the galvanic treatment by puncture, in which the object was to bring about by electrolysis a disintegration of a small portion of the tumor.

Passing to the surgical methods, we should first consider the propriety of trying Hegar's operation, which consists of the removal by abdominal section of the tubes and ovaries, the result of which is to bring about the menopause, and thus arrest the growth of the tumor, as it would be normally arrested had the woman reached the age of forty-five or fifty. This method is best adapted to single, rapidly-growing, and vascular tumors, and is less likely to be of advantage in case of multiple fibroids very dense in texture. The operation is not a very dangerous one, provided there are no adhesions; but it often happens that the ovaries and tubes are so attached down to the surface of the tumor that their removal is impossible. In such a case the operator has two courses before him. He may close the abdominal wound, and the patient will be no worse off than she was before; or he may proceed to remove the body of the uterus, clamping the cervix as a pedicle, and bringing it up to the abdominal wound. This operation has already been done several times in the Woman's Hospital this season, and has already been fully described.

Complete Laceration of the Perineum.

This woman is forty years of age, and has had four children and one miscarriage. The last child was born eleven years ago. Menstruation is regular, but always accompanied with pain. I first saw her about six years ago, when she had a complete laceration of the perineum, having no control whatever over the bowels. I operated upon the perineum at that time, and the operation failed. An operation upon a complete rupture of the perineum is a failure, if the sphincter ani is not perfectly united, and it is a failure if, above the sphincter, there remains the smallest fistula. In this case a small fistula remained. Two years later, the patient being in very much better condition, I performed the operation again, and you see the result before you. The laceration was originally a bad one, a rent extending for some distance up the posterior wall of the vagina. After the second operation, the vaginal wall was entirely united, and the sphincter also; so that now, as she tells you, she has perfect control. I have modified this operation considerably within the last six years, and I believe that I can attribute several failures in times past to the simple fact that I followed the directions given in some text-books, and passed a suture through the margin of the sphincter and completely around the rent in the vagina. This method is very likely to result in failure. A very important point in the operation is to denude a broad surface and bring it together carefully by interrupted sutures. The parts should lie together so easily that there is no tension on the sutures.

Time will not allow the description of this interesting and important operation in detail. I will simply say that for sutures, silver wire is best, though the operation may be done with silk, with catgut, or with silkworm gut. One point is important as to prognosis: if several years have elapsed since the sphincter-muscle was torn apart, that muscle may be so atrophied that no operation will restore it. This case was an

exceptional one in that respect, the sphincter not having undergone atrophy, though eight years had elapsed.

If the case is a recent one, and the sphincter-muscle very rigid, I stretch and manipulate it between the fingers as much as possible, so as to overcome its tendency to spasmodic contraction after the operation. If, after the sutures in the upper part of the wound are introduced, there is some tension, it is well to relieve it by incisions on the right and left side, otherwise the sutures are apt to cut out. The golden rule in this, as in most plastic operations, is to avoid all tension upon the sutures, which should merely serve to keep the parts in accurate apposition. The bowels should be very thoroughly moved before an operation of this kind, and they should be moved within three days of the operation, and never allowed to become constipated. They should be moved by a mild aperient rather than by enema. Castor-oil is probably the best.

Irritability of the Bladder.

This patient, when she first came to us a few weeks ago, had only one complaint, but that was a very serious one. She could not retain her urine more than an hour at a time, and sometimes, if we may take her word for it, she passed water every fifteen minutes during the day, and about every hour during the night. She had become excessively nervous, and showed marked signs of suffering. We found, on examination, no cystitis, no urethritis, and no tenderness on pressing over the bladder. What was rather remarkable about her case was, that the symptoms appeared rather suddenly during convalescence after a miscarriage. We found, on examination, a marked retroversion of the uterus, which, however, was perfectly movable. Placing the woman on her hands and knees, and making gentle pressure posteriorly, the uterus was put in place; and, wishing to expedite matters as much as possible, a retroversion pessary was introduced at once. The patient returned to say, a week later, that she had been almost entirely relieved, and that she could retain her urine easily for four or five hours in daytime, and during the whole night. She has worn the pessary since, and we shall allow her to wear it, probably for some months to come. The explanation of the symptoms in this case is that the uterus, which had undergone only partial involution, had fallen backward, and by its weight had so dragged upon the bladder as to flatten that organ and greatly diminish its capacity. This form of vesical irritability is much more commonly due to retroversion than to a mal-position in the opposite direction. Marked anteflexion often exists without causing any vesical symptoms whatever.

COMMUNICATIONS.

CONSEQUENCES OF ACUTE SUPPURATION OF THE MIDDLE EAR, WITH SPECIAL REFERENCE TO OPENING THE MASTOID.

BY A. R. BAKER, M.D.,
CLEVELAND, OHIO.

The truth of the old saying, that an ounce of prevention is worth a pound of cure, is illustrated nowhere so forcibly as in the treatment of mastoid diseases. It is not altogether improbable that the time may come when the more serious surgical procedures recommended in this paper may no longer be necessary, owing to the early recognition and prompt treatment of mastoid inflammations. Although this is a consummation devoutly to be wished, so long as there is the present ignorance of these diseases among the general practitioners, who usually see and treat them in the early stage, and so long as a running from the ear, or even an earache, is looked upon by the laity as a trifling matter, and so long as the nasal douche and similar appliances are used indiscriminately for treating catarrhal troubles, and so long as no precautions are taken to protect the ears while bathing, we must expect to meet mastoid inflammations, often resulting in serious complications which may require surgical interference to save life.

In order to consider the subject of prophylaxis satisfactorily, it would be necessary to enter into a discussion of the entire pathology, etiology, and treatment of inflammation of the middle ear; but we must content ourselves by saying that "taking cold" must be avoided by daily cold sponge-baths, the avoidance of overheated rooms, the wearing of woolen underclothing in all seasons of the year, and careful attention to secure heavy-soled large shoes. The prompt recognition and treatment of aural complications of the acute exanthemata—especially scarlet fever—are of great importance. The use of the nasal douche should be abandoned. Great care should be taken, when any perforation of the membrana tympani exists, to plug the audi-

tory canal with cotton before bathing. All purulent discharges from the ear should be stopped as soon as possible. In any acute inflammation of the middle ear, it should, if pain be present, be syringed with hot water. The naso-pharyngeal cavity should be closely inspected and treated. The Eustachian tube should be kept pervious, and, if any accumulation of pus or serum be confined within the middle ear, the membrana tympani should be perforated at once. If all pain, fever, and tenderness on pressure be not relieved at once by the above measures, leeches should be applied. If all cases be thus treated promptly, intelligently, and skilfully, few cases of serious mastoid trouble will be encountered; but, even with the most skilful care on our part, we will occasionally meet a case of serious mastoid disease requiring more active surgical interference.

The history of the operation for the opening of the mastoid is one of the most interesting in the entire subject of otology. Probably no operation has been the subject of so many fierce debates, at one time receiving the hearty approval of the entire profession, and the operation even prostituted from its legitimate indications—that of providing a means of escape for the retained products of inflammation—to that of an empirical procedure to relieve a symptom: deafness. At another time the operation fell in such disrepute that von Tröltsch, in 1861, confessed that he would have hesitated to undertake the opening of the mastoid with any instrument but a probe, in a case which he reported, of suppuration of the middle ear, in which Wilde's incision failed to give relief.

There are many surgeons who have been credited with the first performance of this operation, and many of them without doubt deserved credit for their work in this direction; but the honor of establishing this operation upon a firm surgical basis belongs to M. Jasser, a regimental surgeon, in 1776. The details of his first case, as published in the *Journal de Méd., Chim. et Pharm.*, 1793, are so accurate and the indications for the operation so clearly described, that I will give a short abstract of this case.

"A soldier complained of a discharge from his ear. This matter was very fetid, and the patient occasionally experienced severe attacks of fever, accompanied with violent pains, particularly in the right ear. These symptoms were alleviated by blood-letting, laxative and refrigerant remedies, and the application of topical emollients and anodynes. These symptoms returned frequently, and were always treated in a similar manner.

"The patient came to the hospital again in 1776. He had a violent fever and extreme pain. He was bled three times in the space of two days, gentle laxatives were employed, and emollient injections and vapor-baths to the ear; blisters were placed upon the nape of the neck, and, behind the ear, leeches were applied. All these means were successively used and repeated several times. None of them, however, relieved him. The patient continuing to suffer and being without sleep, opium was occasionally administered.

"Ichorous and fetid pus continued to issue from the right ear. At the termination of three weeks, a soft elevation on the mastoid apophysis appeared. Emollient cataplasms were then applied, and the tumefaction disappeared on the following day. Some days after, it again appeared. At last, it was determined to make an incision in the tumor, an inch long. A few drops of a thin and acrid humor, nothing more, issued from it. Poultices were continued, but the pains were as intense as usual. It was then determined to open the bone, and a sound was introduced into the cells of the apophysis. A pectoral infusion, nothing else being at hand, was injected through the opening by means of a syringe. All the injection issued instantly from the right nostril. The pain abated, and, the wound being dressed in the dry manner, the patient went to bed and slept profoundly during the following ten hours. After dinner, the dressing was renewed and the same injection repeated. The discharge from the ear diminished daily, the odor and color of the matter became better, and in eight days he had neither pain nor discharge. The injections were then discontinued and the wound dressed with dry lint only. The bone was kept exposed for some time; but, as no sanies proceeded from it, a cicatrix was permitted to form, which was completed in about three weeks. From that period, the soldier continued to enjoy good health and felt no pain in the ear."[1]

The intelligent manner in which the case was treated by M. Jasser, more than a century ago, and the good sound surgical principles which guided him in his operation, would be creditable to any surgeon of the present time. But, unfortunately, the operation was soon enlarged, and was

[1] Saissy on the Ear, translated from the French by Nathan R. Smith, in 1829.

supposed to be useful in the following cases, as indicated by Arnemann, Professor of Medicine at Göttingen, and his followers:

1. When there is complete deafness, or when deafness pertinaciously increases.

2. When mucous fluids which are secreted in the ear remain there and produce congestion.

3. When the ears are painful and there is heard in them a continual ringing.

4. When the Eustachian tube is obstructed by mucous or other fluids which may be removed by injections.

5. For the purpose of relaxing the membranes and other soft parts of the drum of the ear, and thus giving pliancy to the small bones of the ears.

6. When the cells of the mastoid apophysis contain purulent matter, and when they are carious.

In the latter cases, Saissy very pertinently remarks: "The perforation of the mastoid apophysis is infinitely less painful, and the danger is nearly nothing, because nature accomplishes nearly the whole."

The utility of the operation corresponds to its necessity, and it deserves to be preferred to all other remedies. The reasons why it is preferable are so obvious that I think it is useless to designate them.

It does seem that, with such good authority for performing the operation, that von Tröltsch need not have hesitated to open the mastoid, even with other instruments than a probe. The indications for the operation are so clear in these cases that it seems that no one should hesitate, while in all the other indications, as formulated by Arnemann and his followers, it is as clearly contradicted. It could not possibly do good, and might do infinite harm. But it seems as though some evil genius held sway in the minds of the physicians who have had to do with this operation, urging them to perform it for all kinds of ear-diseases, and then, when some unfortunate accident, as the death of the Danish physician Beyer, who had it performed upon himself for the relief of a chronic proliferous inflammation of the middle ear, occurs, the operation is condemned in all cases and under every circumstance. While I have been a most enthusiastic advocate of the operation, and believe that hundreds of lives have been saved by it, I regret to say that I know of a case having been operated upon, within a few months, for the relief of deafness, and, when no relief was afforded, my published papers were quoted as sanctioning it. A gentleman called upon me, about two years since, for a continual ringing noise in the ear; he also complained of some dizziness and deafness, and insisted upon having an operation performed. I refused, assuring him it would do no good. He then consulted a general surgeon, a man of brilliant attainments—a keen surgical mind—who perforated the mastoid; of course, with no benefit. Now, it is such operations as these that bring it into disrepute. If surgeons only kept in mind the fact that it is not an operation to cure deafness, to cure dizziness, to cure pain, to cure any symptom (although it may incidentally cure all of these), but it is an operation to evacuate retained pus or remove dead bone. I may illustrate, in a crude manner, the object to be gained, upon this skull.

We have here the middle ear in close relations with the cerebral cavity above; the external auditory canal on the outer side, separated by the drum membrane; the amifis of Eustachian tube in front, and the mastoid cells behind.

Now, suppose this large cavity is filled with a purulent secretion; it must escape into the middle ear by a more or less contracted opening, and from there into the external ear through a perforation in the membrana tympani, or possibly through the Eustachian tube into the fauces. Now, what operation is more clearly indicated than to open directly into these cells at this point, and evacuate this purulent matter? The necessity of this procedure is doubly called for, because this focus of purulent secretion is in such close relation with so many important structures. There is above the brain, separated only by the merest shell of bone, often fenestrate in the normal condition. We have in front all the important structures of the middle ear. We have behind and on the inner side the transverse sinus, and on the lower side the jugular vein. The internal carotid artery and the facial nerve are also in very close relation, and not infrequently involved in the inflammatory action.

Some of the most frequent causes which lead to death as the result of mastoid diseases are caries and necrosis of the temporal bone, purulent meningitis, cerebral abscess, pyemia, septic phlebitis, thrombosis, and embolism. I have discussed this subject at some length in a paper read before the Northwestern Ohio Medical Association, and published in the January No., 1888, of the *Cleveland Med. Gazette*, in which I said that "I wish I could impress upon your minds the fact that, excluding the few cases

as the result of traumatic causes, cerebral abscess in the young or middle-aged is almost always the result of chronic purulent suppuration of the middle ear. It seems to have been one of the slowest lessons the medical profession has had to learn, that, when a collection of pus was found in the brain after death, it was a pathological process extending inward, instead of pus formed primarily in the brain and endeavoring to find its way outward. The ease with which an inflammation can be propagated from the middle ear to the meninges, and thence to the brain-substance, can be easily understood by a consideration of the anatomical points involved. The only wonder is that more people do not suffer from meningitis and cerebral abscess. But nature seems to have been leniently disposed toward us in this matter, and, so long as there is a free opening for the discharge of pus, serious brain-lesions are comparatively rare; but, let the outlet be closed, and we immediately have serious trouble. I surmise the frequency of death from cerebral abscess and purulent meningitis is very greatly underestimated by physicians in private practice, where post-mortem examinations are comparatively rare. I have collected notes of over fifty cases of this kind, from various sources, in which post-mortem examinations have proved that death resulted from the consequence of suppuration of the middle ear, either from cerebral abscess or purulent meningitis, and this list could be indefinitely extended by reference to hospital reports and the periodical literature of the past few years.[1]

"Deaths from pyemia, septic phlebitis, thrombosis, and embolism are not infrequent. The transverse sinus is the most frequently affected where it traverses the temporal bone on the inner side of the mastoid process. At this point it is in very close relations to the mastoid cells; but the superior petrosal or cavernous sinuses may be involved, and, when there is a fissure in the lower wall of the tympanic cavity, the jugular vein is very liable to be affected.

"These cases run a very uncertain course, but usually terminate fatally. Death occurs frequently within a day or two, with symptoms of cyanosis and collapse. At other times, the course of the disease is a chronic one. There may be chills, followed by long periods of comparative good health; there may be metastatic abscesses and all the series of symptoms of pyemia from other causes."

The indications for opening the mastoid process, as most recently stated, may be summarized as follows:[1]

1. Purulent inflammation in the mastoid process appearing in the course of suppuration of the middle ear when persistent severe pain in the bone cannot be subdued by the application of the ice-bag, leeches, or by Wilde's incision. (Schwartz.)

2. Painful inflammation in the mastoid process occurring in acute and chronic suppuration of the middle ear, in consequence of growths filling up the external meatus or the tympanic cavity. When attempts to remove the obstacle to the free escape of pus have failed, the operation is imperative. (Grüning.)

The operation is indicated even though the soft parts over the mastoid are not swollen or infiltrated. (Politzer.)

3. When the posterior superior wall of the meatus is bulging, and when, after incision, the abscess is not emptied, and the symptoms of retention of pus continue. (Toynbee, Duplay.)

4. Persistent pain and tenderness in the mastoid process, lasting for days or weeks, in which there is probably an osseous abscess not communicating with the tympanic cavity. (Politzer.)

5. In every suppuration of the middle ear combined with inflammation of the mastoid process, in which fever, vertigo, and headache are developed during the course of the affection, which may indicate a dangerous complication. In such cases the indications for the operation are vital. (Politzer, Roosa, Buck.)

It will be seen there is no allusion to deafness, noises in the ear, dizziness, etc., and I will repeat once more that the indications are simply for the evacuation of the products of inflammation and the removal of dead or carious bone. I will grant that there may be cases in which it is impossible to say whether there is retained pus or carious bone; but, if the symptoms are at all alarming, the surgeon would be justified in giving the patient the benefit of the doubt by making an exploratory operation.

There is much diversity of opinion as to the proper time to perform the operation of opening the mastoid. In a given case of acute inflammation of the mastoid, I have

[1] See Politzer on Diseases of the Ear, p. 526; Roosa, Treatise on Diseases of the Ear, Table of Fatal Cases, p. 554.

[1] See article by the writer, on indications for opening the mastoid process, in the *Cleveland Med. Gazette* for February, 1886.

been in the habit of pursuing the following plan of treatment: When the first indication of pain and tenderness appears in the region of the mastoid, leeches are applied, and the ear is syringed frequently with hot water. If the pain continues and there is noticeable swelling over the mastoid, Wilde's incision is made down to and including the periosteum, and hot poultices applied. In the vast majority of cases this is all that is necessary, especially if the throat and ear are properly treated, and a free exit of pus maintained by the diligent use of Politzer's bag and the syringe.

Of course, if there is any obstruction to the free discharge of pus due to infected serum, polypi, exostoses, or any other cause, it must be removed. If the pain continues and the swelling is not promptly relieved by Wilde's incision, no time should be lost in perforating the bone, as the dangers from delay are many.

The necessity for prompt action is as urgent, and the indications for its performance somewhat similar to that for the opening of a felon. Delay in the one case may result in the loss of a finger; in the other, of a life.

As this is an operation that every general practitioner may be called upon to perform, owing to the necessity for immediate relief many times before skilled assistance can be secured.

If you will pardon me for appearing pedantic, I will describe somewhat minutely the manner of performing the operation, and exhibit a few of the instruments made use of.

In making Wilde's incision, any stout sharp scalpel will answer all practical purposes. The incision should be made from below upward, so as to avoid any danger of injuring the structures in the neck. Anyone not having experience will be surprised to find how deeply the bone is situated in this region, especially if the tissues are swollen and infiltrated. It is not necessary to avoid the posterior auricular artery, as the course of this vessel is so variable that you will probably not succeed. The free hemorrhage is salutary rather than otherwise, and can be controlled by pressure if necessary. The incision should be made close to the auricle, an inch and a half in length, and connected with a shorter horizontal one slightly above the linear temporalis. The teguments, together with the periosteum, are then reflected backward and downward, placing the entire mastoid under inspection. If any sinus exist, they will be readily discovered, and the operation will consist in simply enlarging the existing opening. Formerly trepans were used for perforating the bone, and these were replaced by drills, which are still used by Buck, Jacobi, Lucae, and a few others. But, owing to their soiling the wound with splinters, and the difficulty with which they are controlled when advancing in the deep parts, I very much prefer the chisel, as recommended by Schwartz. The drills always seem to me like dangerous instruments; if, unfortunately, the cerebral cavity or one of the sinus be perforated, it would be almost impossible to avoid wounding the meninges, while, with the chisel, little or no harm would result, as every step of the operation is under the eye of the surgeon. It is generally necessary to administer an anæsthetic, although I have performed the operation several times without doing so. The linea temporalis and the more or less strongly developed protuberance on the posterior superior orifice of the osseous meatus, so strongly urged by authors, are very nice guides theoretically, or to point out an exceptional skull in the class-room, but practically are seldom well enough developed to be of any use to the operator. The best guide is to take the superior wall of the meatus as the upper boundary, and the angle formed by the plane of the mastoid with the posterior wall of the external meatus for the anterior boundary, when opening the mastoid. This is best determined by pressing the finger into the meatus. Often in children, and when the bone is diseased in adults, the cortical plate of bone can be removed with the hand-chisel, and we come at once upon the pus-cavity, or diploë, or cholesteatomatous epidermic masses, or a sequestrum of dead bone, or bleeding granulation-tissue, or whatever the case may present. Sometimes the external plate is very thick, and we have to chisel our way carefully for almost an inch before reaching the diploë, or may even find the entire mastoid process sclerosed.

No absolute rule can be given as to the depth it is safe to penetrate. Schwartz says "Never go deeper than 25 mm." Buck says "It is better to place the extreme limit at 20 mm."—about three-fourths of an inch.[1]

Occasionally in old chronic cases the entire mastoid process will be found sclerosed and of ivory hardness. In these cases it is not best to seek for mastoid cells which do not exist, but endeavor to penetrate the

[1] Baker. Cleveland Med. Gazette, Feb., 1886, p. 168.

aurum mastoidum, and thus reach the middle ear; but even this may be gained only with great difficulty, and, unless there is some obstruction to the free escape of pus through the external meatus, which cannot be removed, it is often best to desist from further attempts to reach the middle ear when this condition is found to exist.

In addition to the chisels, a bone knife with a concave cutting-edge for enlarging the external osseous shell, a sharp spoon for removing the granulation-tissue, diploë, etc., a few blunt and sharp pointed hooks, dressing-forceps, probes, ligature, etc., such as are found in any pocket instrument-case, will be required; also a good syringe and a carbolized bichloride, or whatever antiseptic solution the surgeon is in the habit of using. I prefer powdered iodoform dusted into the wound to any other dressing, and, instead of the various drainage-tubes or lead nails so highly recommended by some, I use a simple piece of cloth well saturated with iodoform.

I am aware that this is considered by many a serious operation, and Politzer has said "that no one should operate on the living without having performed the operation at least forty or fifty times on the dead." Yet I believe that no physician should permit a patient to die from the consequences of acute suppuration of the middle ear without first giving him the benefit of this operation, as the indications for its performance are so imperative.

MORPHINE AS A CAUSE OF ACNE ROSACEA.

BY CHEVALIER Q. JACKSON, M.D.,
PITTSBURGH, PA.

Rosacea, one of the most common of the dermatoses, is attributed, by dermatological writers, to certain reflex vascular disturbances of the facial circulation, consequent upon stomachal, intestinal, and uterine derangements. While this is true in a certain proportion of cases, there are many which consult the dermatologist in which no such disturbance exists. In a large number of the latter class of cases, I have found the morphine habit, which, at the present time, is so startlingly prevalent, to be the chief etiological factor. Since I first observed this, a number of cases have come under my observation, in which the rosacea was directly attributable to the use of this narcotic. As all these cases were very similar, it will serve my purpose sufficiently well to give the condition and clinical history of the first three.

Case I.—M. M., 25 years old, a bookkeeper by occupation, came to my office for the treatment of a marked outbreak of acne rosacea, involving the integument of the nose and a small portion of the face. On questioning him, I learned that the trouble had commenced about a year previously, in the form of a most severe pruritus. A few months later, there appeared a faint red blush, with sometimes a single isolated papule. This condition at that time was not constant, being unpleasantly prominent only after a more than usually excessive indulgence in morphine, or after a prolonged spell of cold inclement weather. It was usually accompanied by more or less seborrhœa, and was soon followed by a permanent redness, with gradually dilating capillaries, together with a swollen and more or less pustular condition of the dermal glands—as the patient himself expressed it, "mattery pimples."

At the time he came under my care, the disease was well advanced in what has been somewhat arbitrarily called the second stage of the disease, and, had it not been arrested, would, in all probability, have shortly crossed the arbitrary and ill-defined line into the third stage, for there was already present extensive thickening and infiltration, together with a decidedly hypertrophic condition, together with incipient tendency to lobulate, round, elastic outgrowths. The glands were enlarged, swollen, pustular, and slightly painful, with here and there large comedones. The vessels, enormously dilated, were to be seen ramifying in every direction, the morbid process extending, however, but little beyond the nose. The parts were warm to the touch, and would often, after exposure to sudden changes of temperature, become purple. A section cut from near the ala nasi showed, on microscopic examination, a markedly thickened mucous layer, infiltrated with inflammatory new formation, while the epithelial layer, on the contrary, was much thinner than normal, being almost absent in some locations. The walls of the vessels cut in section were much hypertrophied.

In searching for the cause of the local morbid process in this case, I ascertained that he was a total abstainer (which I had good reason to believe, as far as alcohol was concerned), and that he had had no gastric disturbance until a few weeks before he consulted me. The entire alimentary canal was in fairly good condition, with the exception of some slight constipation, of which he had relieved himself by an occasional Seidlitz

powder. His general appearance indicated average health, save for a constant nervous movement of the eyeball and markedly contracted pupil. These two latter facts, together with the fact that the trouble had commenced with a severe pruritus, led me to make inquiries to ascertain if the patient was addicted to the use of opium or its alkaloid. This he strenuously denied, until, under the pretense of wishing to look for the eruption on other portions of the body, I had him remove the clothing from his lower limbs, when I discovered that a portion of the anterior surface of the left thigh was dotted here and there with small papular and pustular elevations, which, after slight hesitation, the patient acknowledged to be the result of the use of the hypodermic syringe. He stated that for a year and a half he had been in the habit of injecting morphine subcutaneously into his thigh every night at bedtime. At first, he took in this way one-eighth of a grain; later, he increased the quantity to a quarter-grain, which dose he had not exceeded. He claimed he had only injected the drug once daily, and that always at bedtime, which accounts, probably, for the absence of stomach trouble. The patient also stated that he always took a cup of strong coffee in the morning before rising, which would further tend to neutralize the tendency of the morphine to cause nausea and gastric irritability. The papules and pustules spoken of above as being produced at the point of injection may have been due to the crude and ill-made rusty needle used, or to dirt, lint, oil, or other foreign matter being injected; or, as I have occasionally seen, to an idiosyncratic sensitiveness of the skin to morphine, which manifests itself in a papule at the site of injection.

Acting on the theory that the morphine was the cause of the rosacea, I directed the patient to abandon its use gradually during a period of not less than two months, reducing the amount taken by one-sixteenth of a grain at regular periods of two weeks, meanwhile having him take sufficient doses of the bromides to enable him to sleep, giving him during the day full doses of caffeine, with the hope that it would counteract the effect on the rosacea of the morphine he was taking. During this time, no local treatment was instituted.

At the end of the two months, the condition of the rosacea was markedly improved; the color had become paler and the acne papules had almost disappeared. The patient was now compelled to give up entirely the use of morphine. The bromides were continued for two weeks and then stopped. At the end of four months after having stopped the morphine, all that remained of the rosacea was a few scars, with some slight hypertrophy and a number of dilated capillaries. The hypertrophy was removed by daily applications of the galvanic current, and the enlarged vessels were obliterated by electrolysis, using the needle with which superfluous hair is removed.

Case II.—A. E. W., 35 years old. The course of the rosacea, in this case, was very similar to that of the first case, except that it was much slower in development, and that the morphine was taken by the stomach, in smaller doses, and from twice to three times daily. The skin of the nose was somewhat thickened and infiltrated, but there were few acne papules, and altogether the disease manifested itself in a much milder form than in the preceding case.

I placed this patient under the same restrictions as to morphine, reducing at first the quantity taken at each dose, and finally the number of doses daily, until the habit was entirely abandoned. I refrained from all treatment in this case, save a simple placebo given internally. In a remarkably short time, the cutaneous tissues commenced to resume their natural appearance, and continued steadily to improve until, at the end of three months, the affection had disappeared, except a slight erythema, extending over a portion of the area originally covered by the disease. This erythematous condition of the surface has since disappeared under simple local treatment.

This patient stated that he had never suffered with gastric disturbances, stating that his appetite was always good, with little or no constipation, and a very thorough search failed to indicate any other cause than the morphine for the typical rosacea which existed when I first saw him.

Case III.—Mrs. ——, 24 years old. This woman, an actress, had been using morphine for a number of years, but never continuously until recently. Some time before the appearance of the rosacea, she had commenced taking the drug for the relief of a very severe dysmenorrhœa, from which she suffered severely up to about a year before she consulted me. She would take the morphine hypodermically during a week, commencing two days before she was unwell, at which time the pain made its appearance. Shortly after beginning the use of the drug, she was troubled with a severe itching of the

nose, which, at first, continued only through the week during which she used the narcotic, disappearing in the interval during which she took none. But, by degrees, the pruritus began to linger for a gradually increasing period of time, until it was almost constant. At the same time, the sebaceous glands began to enlarge and take on an inflammatory condition, forming papules and pustules. This condition was always much ameliorated, and would, at times, almost disappear, in the interval between the periods, only to return at the next menstruation, if she took morphine. She herself had noticed that, when she took chloral instead of the opium alkaloid, the rosacea did not show the least exacerbation; and she would have used the former drug, in preference to the latter, if it had had sufficient anodyne qualities to relieve the pains of the dysmenorrhœa, which finally became so intense that she was led to consult a New York gynæcologist for permanent relief. As nearly as I could learn from the patient, he told her she was suffering from anteversion associated with a narrow contracted canal. He used forcible dilatation, under an anæsthetic, which entirely removed the dysmenorrhœa, since which time (about a year before I saw her) she has menstruated regularly, without any pain whatever, or any symptom of uterine disturbance; and a periodical examination, made every two months during the year by the same gynæcologist, failed to discover any trace of an abnormal condition of any kind. During this period, however, the rosacea had not been improving, but, on the contrary, was rapidly developing lobules and becoming more and more disfiguring, which the patient herself thought was due to the morphine, the use of which she was unable to discontinue, although the pain had disappeared.

At the time I saw her, the condition of the integument indicated a most marked case of acne rosacea, gradually developing the symptoms which indicate the third stage.

As she was too confirmed in the morphine habit to be broken of it by any other means, I had her husband place her in a private hospital for the treatment of opium habitués, with instructions that she should have absolutely no treatment whatever, save the regular house treatment, to overcome the cravings of the system for the narcotic.

Three months later, she came into my office, with a nose of which she said she was not ashamed. Upon examination, I found that all that remained of the original disfigurement was a number of scars and a slightly hypertrophic condition of the skin. There also remained a few dilated capillaries and some stout bristly hairs that had commenced to develop, owing to the increased nutrition of the parts. These I removed, together with the dilated capillaries, by electrolysis.

Now, the history of these three cases indicates so clearly that the morphine had a primary causative relation to the rosacea, that scarcely any argument is required to establish the fact. In the first case, it might be argued that the drug was only indirectly the cause, acting simply by creating gastric, intestinal, and other disturbance which, in turn, produced the skin-affection, were it not for the fact, which I stated before, that all the functions were not interfered with by the drug, which was probably due to the manner in which it was taken.

In the third case, it would be possible to attribute the rosacea to uterine derangement, were it not for the fact that the removal of the dysmenorrhœa did not in any way benefit the condition of the nasal integument, which continued to grow worse as rapidly as before. Surely, if the morbid process located in the skin of the nose was due to the uterine trouble present, the removal of the latter would cause the rosacea to disappear. I am aware that it will be argued that there may have remained some remnant of the former uterine trouble to keep up the reflex irritation; but, if such existed, it failed to show itself in any symptom whatever. There was not the slightest endometritis, cervicitis, erosion, displacement, or any abnormal condition, ovarian, tubal, vaginal, uterine, stomachal, nervous, or intestinal. The patient did not "touch, taste, or handle" alcoholic liquors of any kind; was neither anæmic nor chlorotic, being plump and healthy save for an abnormal paleness of the skin (except on the nose) and the contracted pupils.

In all these cases there was a marked pruritus, commencing before the appearance of the eruption and continuing during the progress of the trouble, to a greater or less extent. This pruritus is seldom if ever present in any appreciable degree in rosacea from any other cause, but is an almost constant physiological action of morphine. The itching causes the patient to rub, scratch, and otherwise irritate the parts, thus causing an inflammatory condition of the surface, which would, perhaps, to some extent, tend to the development of a rosaceous condition. I am certain, however, that morphine, when taken into the system, has a

direct selective action on the nasal integument. The fact of its producing pruritus at this point, and so very slightly or not at all over the general surface, indicates this.

I have now under my care three cases of eczema rubrum, in which a small dose of morphine, given three or four nights in succession, will produce a crop of acne papules, with a pruritic and erythematous condition of the skin of the nose.

On mentioning my ideas on this subject to a medical friend of mine, he told me that he occasionally took a quarter-grain dose of morphine, while traveling, to enable him to sleep on the cars, and that it almost invariably produced a bright red papule, very sensitive to the touch, and so disfiguring as to lead him to substitute for morphine paraldehyde, although the former was so much more inconvenient to take.

These facts, all taken together and viewed in conjunction with the above-described cases, indicate, I think, very clearly, that morphine has a direct action on the blood and nervous supply of the nose. Whether this action is through the vaso-motor, sympathetic, or general nervous system remains to be investigated. My own opinion is that it is due to the passive hyperæmia produced by the drug. The well-known physiological action of morphine is to lower arterial tension, dilate the arterioles, and produce this passive congestion, which is always present in the early stages of every case of rosacea, from whatever cause produced. Following this passive hyperæmia would be the inevitable reaction, which would produce the sensation of pruritus the same as the reaction from excessive cold. Further, this condition of passive congestion, if kept up or frequently renewed, would certainly lead to an altered condition of the nutrition of the parts, causing hypertrophy and other symptoms of rosacea, entirely independent of any local direct irritation by rubbing the nose for relief of the pruritus; this mechanical irritation, however, probably aids in the causation of the pathological processes.

As it is not always possible to elicit from the patient a confession of the use of opium or morphine, the fact will usually have to be arrived at from the general aspect of the patient. Dilated blood-vessels and other objective symptoms, together with the subjective symptom of marked local pruritus, are usually the first manifestations of the disease. This is in marked contrast to ordinary rosacea, in which pruritus never occurs to any appreciable extent.

In any case of this most obstinate malady, a cure always depends on the discovery and removal of the exciting cause, and, as this is often difficult to discover, any light thrown on the subject will always be welcome, not only to the dermatologist, but to the general practitioner as well. Let this be my apology for presenting this paper.

ON THE TOXICITY OF THE "FRUIT JUICES."

BY W. H. MORSE, M.D.,
WESTFIELD, N. J.

It is not alone in alcoholic liquors that fusel oil is an available poison, though, for obvious reasons, the fact is one that is not of general recognition even by physicians. The chemist does not need to be told that the poisonous oil is afforded in much of the cheap "soda water" and confectionery. There is just ground for placing not a little of the "soda water" in the same category with the "rot-gut" whiskies of the saloons. Not that it enters into the composition of the carbonic-acid water commonly known by the name of "soda water"—an allegation that any manufacturer would be justified in denominating a distinctive libel. The trashiest stuff sold at the soda fountain would not merit such a charge; indeed, the toxic water is more apt to be the article dispensed from the most reputable and "fashion-patronized" fountain, though it is, as well, dispensed at the "cheap-john" stand and the three-cent-a-glass stores.

It is made an ingredient by the flavors of the water—the "pure fruit juices" of the able manufacturing chemist. What is a "pure fruit juice" or a "fruit essence"? Looking at the matter casually, the innocent consumer would be ready with but one reply: "A 'fruit juice' must be the juice of a fruit." That is one way of looking at it. It is true that there are the juices of fruit which are used as "fruit juices," but I think that I do not err in stating, upon a recent estimate, that, for every pound of the real juice that is used in the drug-stores, there are used from 60 to 100 pounds of artificial "juices." These comprise a large list: strawberry, raspberry, pineapple, wild cherry, peach, prune, orange, elderberry, fig, currant, blackberry, raisin, several varieties of grape and pear, quince, cranberry, lemon, lime, apple, and, in fine, "any fruit desired."

There are many kinds of these factitious preparations, but practically the varieties are but two, namely: those in which amylic

alcohol is used, and those which employ the ethylic. This is explained in this way: Several of the compound ethers possess the odor and flavor of certain fruits. Present in these compounds are the two simple ethers known as the ethylic and amylic. Each of these has a base and an alcohol; that of ethylic ether corresponding to ethylic alcohol, and that of amylic ether to amylic alcohol or fusel oil. Chemically speaking, these alcohols are, respectively, hydrated oxides of ethyl and amyl. It will therefore be apparent that the essential bases are the alcohols; and obviously—for commercial reasons—the amylic alcohol has the precedence, and is at once the most common and the most culpable of the two artificial preparations.

I happen to know—and the knowledge is scarcely of a kind to be a matter for pride—that the manufacturer prefers the amylic alcohol, arguing that it "works" better than the ethylic, and is "cheaper." Let us look at the "inner workings" of this manufacture.

Take, for instance, a few of the most popular juices. Pineapple juice contains ten parts of butyrate of amyl; strawberry, two of butyrate and three of acetate of amyl; raspberry, one of each; apple and lemon, ten each of valerianate of amyl; orange and pear, ten each of acetate of amyl. Other juices are "all of a kind."

The genesis of acetate, butyrate, and valerianate of amyl is chemically suggestive. The first-named is prepared by distilling one part of fusel oil or rank amylic alcohol with one of concentrated sulphuric acid and two of acetate of potassium, subsequently freeing from free acid and water. The valerianate is made by mixing four parts each of amylic alcohol and sulphuric acid, adding five parts of valerianic acid, and subsequently washing and purifying.

The acetate of amyl possesses in a most remarkable degree the taste and smell of the Jargonelle pear, and it is an alcoholic solution of it that forms the "pure juice of the Jargonelle pear." Add, to 15 parts of it, one-half of one part of acetic ether, and in 100 parts of alcohol it forms "bergamot pear juice." Substitute butyric for acetic ether, and the solution is "banana juice." Again, an alcoholic solution of valerianate of amyl, in the proportion of one part to six of alcohol, forms "apple juice."

On the other hand, the acetate, the butyrate, and valerianate of ethyl are employed in the same kind of manufacture, but the essence or "juice," having the oxides of ethyl as constituent of their bases, are "weak." By this term is to be understood a lack of popularity—poor sellers, unpopular. Of this kind are such "juices" as melon, plum, gooseberry, grape, peach, and cherry, all of which contain the ethylic and lack the amylic oxides. To instance more particularly: One part of butyrate of ethyl in six to ten of alcohol forms "pineapple juice." This "juice"—together with "quince," one part pelargonate of ethyl in six of alcohol—constitutes the only popular "juice" of the ethylic series. But the "pineapple juice," it must be remembered, contains, nowadays, ten parts of butyrate of amyl to five of butyrate of ethyl, constituting the "improved juice."

Inquiry made of forty-seven New York, Philadelphia, Boston, and Cincinnati manufacturers of artificial juices, or, in the parlance of the average advertisement, "pure fruit juices," resulted in obtaining the following list of twelve "leaders": Pineapple, strawberry, raspberry, grape, apple, orange, pear, lemon, cherry, plum, apricot, and peach. One hundred and sixteen druggists were asked to "signify which of these twelve were the best sellers at the fountain." I will not give the lengthy "vote" in detail, but it will suffice that I found, in summing it up, that the favorite flavors with customers were as follows: Pineapple, lemon, orange, pear, apple, and peach.

It will be noticed that it is alone the peach juice that is popular, of the ethylic juices. There are some new favorites, not included in the list; but, without exception, they have basic amylic oxides.

It should, perhaps, be noted that, in addition to the ethylic and amylic oxides, some of the "juices" contain other minor constituents, as glycerin, chloroform, aldehyde, nitric ether, sebacic ether, salicylate of methyl, certain acids, and three or four ethylic salts of inferior valuation. These ingredients are used in modification, to bring about or preserve more nearly the fruitic resemblance. To procure a "natural color," certain other chemicals are employed. As to any combination being made with the true essences, I have only to say that orange "juice" does contain ten parts essence of orange; but it is the one solitary instance in kind, though lemon, raspberry, and grape purchase an acid taste with tartaric and succinic acids.

In a burst of confidence, one manufacturer boasted that no one could distinguish his syrups made with artificial juices, from the

officinal syrups; but, although he made a very good and popular line of syrups, factitious character considered, I had the pleasure of showing him that his lemon, raspberry, strawberry, and pineapple syrups were utterly unlike those which are officinally prepared from the fruits after the formula of syrup of lemon.

Three other points were followed out:

1. As to the preference of known alcoholic liquor drinkers.

The favorite flavor with this class was found to be the juices of the amylic series—a significant fact.

2. In the matter of the so-called "soda-water intemperance," as to the preference of those so addicted.

It did not require a very close search to discover that the preference of this class was for soda water flavored with the amylic oxides.

3. As to any preference which physicians have in "prescribing" soda water.

The outcome of this line of research was the discovery that, where medical men prescribed other than "plain soda water," they were "always careful to specify the pure fruit juices." "But if you do not have such?" I asked a prominent pharmacist. "Well," he said, with a knowing wink, "it saves me the doctors' custom, if I'm all out, excepting peach." Peach juice (artificial) does not contain fusel oil.

The plain fact — and ever becoming plainer and plainer as I investigated the matter—was that the artificial had largely crowded the natural juices to the wall, and that, though there are artificial "juices" which are of chemical purity and non-injurious to the health, the favorite artificial "juices" are those which are base with fusel oil. More of these than of the other are manufactured and drunk, and, as a rule, the baser they are with fusel oil, the greater is their popularity. It is also just to remark that these factitious essences are extensively used for flavoring candies, ices, and jellies, to the greater or lesser exclusion of the natural juices; and that, as in the case of the fruit syrups, both manufacturer and retailer prefer those toxic with the fusel oil.

The question will occur: Are we, then, to rank soda water and confectionery which are flavored with a fusel-oil product as of a toxic character? We can make but one answer: A poison is a poison, whatever its dose or form of exhibition. Strychnia, arsenic, fusel oil, or any other poison, is of a toxic character in large and in small doses. The only way to prevent the action of a poison is to decline it the privilege of acting. The minute dose may not procure any harm, but it is not always of such characterization, and the best plan is to leave it alone altogether. My investigations go to show that the class of fruit juices in question is deleterious, and, if the law for the sale of poisons will not touch the case, there is a statute governing adulteration. The demand should be for pure natural fruit juices, and, next to them, for pure artificial juices. There is no excuse for the manufacture and sale of those that are more or less toxic.

SKETCHES FROM THE NOTE-BOOK OF A COUNTRY DOCTOR.

BY H. J. CRUMPTON, M.D.,
SAUCELITO, CAL.

Gun-shot Wound of the Scalp; Recovery.

A five-year-old boy managed to elevate and fire a loaded gun in such direction as to inflict an ugly scalp-wound on the person of his nurse, about 19 years old, who was stooping over and looking out of an open window. The child was some ten feet behind her. The charge of small shot struck near the posterior inferior angle of the left parietal bone, and, after ploughing a ragged furrow some two inches in length forward and upward along the surface of that bone, glanced off over the top of the head and passed out through the open window. Outside the immediate track of the charge, the scalp was loosened from the cranial bones over quite a surface. The following conversation occurred soon after my arrival: "Is she seriously injured?" "Yes." "Do you consider her dangerously wounded?" "Yes; all such injuries to the head are to be considered dangerous. During the war between the States, a serious death-rate followed what were at first considered simple scalp-wounds." This was not very reassuring; in fact, it was rather exasperating to those present, who saw there was little or no bleeding, and had just been told no shot had penetrated, that the skull had apparently escaped injury other than its denudation and loss of periosteum over not a very large surface. Bystanders said that immediately after the shot the girl showed much alarm; said she would soon die, asked them to pray for her, and soon after passed into syncope. She was in a semi-comatose state when I saw her, half an hour afterward, with feeble

irregular heart-action and labored respiration. She soon rallied, however, under guarded stimulation and friction to extremities.

The hair adjacent to the wound being clipped, the wound was cleared of foreign matter, including a few stray shot; the loosened scalp readjusted, every particle or shred of which, not entirely detached, no matter how badly torn and lacerated, was utilized as a temporary covering for the naked bone, with the hope of avoiding necrosis. Over the wound a compress, retained in place by a properly-adjusted bandage, was kept saturated with

Fluid extract of calendula	2 parts
Whiskey	2 "
Spring-water	4 "

The broken-down tissues with which the "furrow" had been roofed over soon degenerated into a hard shell-like eschar tissue, but remained an admirable covering, hermetically sealing the wound for the first ten days, during which there was not one drop of suppuration or discharge of any sort, little or no tumefaction, and scarcely a blush of inflammation. The pulse and temperature remained nearly normal, and all the conditions as favorable as they could be. On or about the tenth day, a corner of the covering was unfortunately detached, when the process of repair was shown to have progressed admirably. Now, atmospheric air, doubtless loaded with micro-organisms, for the first time gained access to the wound, and this was soon followed by a nasty sanious discharge, with well-marked constitutional disturbance. All this, however, was soon corrected by changing the dressing to a sublimate solution (1 to 2000), with internal administration of a few doses of quinine and iron. Soon all the cap was taken off, thus converting the injured surface into an open granulating wound. The principal dressing afterward was iodoform in vaseline. Everything progressed favorably to the end; professional visits were discontinued on the twentieth day, and the girl soon after resumed her duties. She complained, however, of periodical pain radiating from the seat of injury, and slight ringing in the ears, and dimness of vision. Taking everything into consideration, however, the extent of injury, the absence of suppuration, slight inflammation, continuous healthy granulation, followed by the naked bone being so admirably roofed in by substantial cicatrization, one felt excusable for indulging in a little self-praise, and holding a favorable opinion of the dressings used, sentiments not largely shared in by any of the household; some of them facetiously called the first a "marigold cocktail." But it is not always a calamity to have one's merit measured by other than his own standard, as we are all prone to lose sight of the healing powers of unaided nature.

Lacerated Scalp Wound.

In pioneer-days, before this territory entered Statehood, two drunken miners ended a fight by one receiving a blow across the top of the head with the blade of a steel mining-shovel, which severed the scalp from the skull over a large surface, so that the scalp was found turned over and hanging down the back of the neck. This was my first case in surgery. In the absence of all ordinary appliances, treatment consisted in pulling the scalp back to nearly its old place, where it was successfully retained—thanks to the suggestions and assistance of a common-sense old sailor present—by tying together tufts of the long dirty hair from opposite sides of the approximated edges of the wound. The latter was then covered with compress and bandage, and kept continuously wet with a decoction of black-oak bark for the ensuing two weeks. During this time, the wound was never uncovered or examined. Union must have been immediate, as there never was any discharge or constitutional disturbance. At the end of the two weeks referred to, the whole nasty mass—everything—down to the shaved scalp, was removed, with some difficulty, when everything was found nicely healed, and the patient soon resumed work. Doubtless the tannin in the oak bark acted nicely as an antiseptic healing agent; but the old stager credited his prompt recovery to the amount of whiskey he used—he had always drunk all he could get.

Enforced Consultation.

In response, once, to a call "to come quick," I found that a primipara—a splendid specimen of womanly vigor—had been in labor twenty-four hours, under the care of her father and an old woman. The old man was a sort of preacher-doctor. He said he never got "stuck" before. He, it seems, gave medicine besides relying largely on prayer-cure. The old woman said she had been a midwife "nigh on to thirty year," and this was the first time she had to have the aid of a doctor. Of course, common gallantry prompted the young practitioner to express himself as complimented to be thus associated with two such

veterans! The sufferer was found to have a well-formed roomy pelvis, and there was an ordinary vertex presentation, so the tedious labor had to be charged to "meddlesome midwifery." Everything was soon over, as was announced by lusty crying of the new-comer. Both did well. The mother expressed gratitude for her prompt relief; but the old couple robbed me of all glory by asserting that they had "jest about fetched her around" before my arrival, but they could not agree as to whether it was the result of the old man's prayers or the old woman's last dose of asafetida.

Not long afterward, the old man had an ugly attack of dysentery. He insisted on being his own doctor and going outdoors to pass frequent bloody dejections, till too weak to travel. After consenting to have me called, as soon as he was scared into remaining in a recumbent position and using the bedpan, in a little while his troubles were over. When, however, an effort was made to draw from him some expression of acknowledgment of my humble agency in his prompt relief, his thoughts were found to be running in a different direction, as shown by his saying: "Well, Doc, I didn't think you'd keer, and I had some truck in the house—some 'intment—which I knowed was bound to fetch it; so I jest rubbed some of it on my fundim-e-n-t, and I felt it tech the spot right away. I knowed it was bound to fetch it."

The Medical Witness.

As doctors and lawyers are grouped together by most laymen as a lot of vampires living off the substance and misfortunes of others, those of the two callings ought to stand together in an alliance defensive, if not offensive; and, usually, medical men do feel kindly toward the legal fraternity. The latter have a queer way, however, of reciprocating, as is shown in their promptness to take charge of blackmailing schemes, sometimes called suits for malpractice, and as shown in their treatment of medical witnesses when dragged into court and subjected to raking cross-fire on the witness-stand. There are cases, however, in which the latter procedure is excusable, as when adolescence rushes in where experience is unwilling to go, or in the case of some medical fledgling assuming to be a medical expert, and willingly—yes, gladly—taking the stand, pregnant with the idea that he has important statements to make for the enlightenment of court and jury. But, when he gets through, it is with a change of heart: he knows no one has been enlightened but himself, and he has been forced to expose all his ignorances, and not permitted to tell anything about which he has a lucid idea. Once, when younger than now, it was my fate to figure in some such rôle in a divorce case, in which the wife sued her rich husband for a legal separation and alimony. One of her grievances was that he charged that, at marriage, she had gonorrhœa, with which she infected him. My evidence, given with the earnestness and zeal of one strong in the faith that she was a pure, slandered, wronged woman, was to the effect that, shortly before marriage, she was under my treatment for leucorrhœa, an ailment that even an expert might mistake for gonorrhœa; that a husband cohabiting with a wife thus afflicted might take on non-specific urethritis, and I gave it as my unqualified opinion that such were the conditions in the case pending. Well, she got her divorce, but the presiding judge refused to grant alimony, whether by reason of, or in spite of, my medical testimony that functionary never stated. Not long afterward, one who stood high as a nice moral young man called to see me, a picture of wretchedness and woe. He said there was something seriously wrong with his "private parts," he could not imagine what. Upon examination, an effort was made to relieve his mental anguish by the assurance that he could soon be relieved, as it was only a plain uncomplicated case of old-fashioned clap. This announcement was a shock and surprise. He said it could not be—it was impossible. In total disregard of these protestations, it was suggested that he had better tell where he got it, as such information might have an important bearing on treatment; whereupon, after a little hesitancy, he lifted up his voice and said: "Well, Doc, I never fornicated with but one woman in my life, and never would have touched her had you not given her so excellent a character when a witness in her divorce case." Thus the wretch made me a party to his woes, and, as soon as cured, skipped away into the unknown, after beating me out of my fee.

"Such is (professional) life in the far West."

—There were 377 cases of scarlet fever and 66 deaths in New York City during the week ending August 14; and 709 cases of measles and 59 deaths during the same period.

Society Reports.

OHIO STATE MEDICAL SOCIETY.

FORTY-THIRD ANNUAL SESSION, AT COLUMBUS, JUNE 13, 14, AND 15, 1888.

The President, Dr. S. F. Forbes, in the chair.

Mayor Bruck, of Columbus, delivered an Address of Welcome. He quoted the old saying that "the sun shines on our successes and the earth hides our blunders." The successes, he thought, exceeded the blunders very greatly.

Reports of the Secretary, Treasurer, and various committees were made. Also the reports of the delegates to the American and British Medical Associations.

Report of Delegate to British Medical Association.

Dr. E. S. McKee, of Cincinnati, made his report as delegate to the British Medical Association. He reported his visit one of very great pleasure and instruction. The British Association he found superior to the American in some respects, inferior in a few, and similar in many. Politics play quite as prominent a part in the British as in the American Association, and sectional strifes, he said, were frequent and bitter. The English doctor, as is perfectly natural for an Englishman, thinks himself superior to his Scotch or Irish brother. This shows itself in various ways, among others in the advertisement of various charitable institutions that wish to fill vacancies in their staffs. Their advertisements read to the effect that no Irish or Scotch need apply. This the Irish and Scotch naturally resent. This resentment took the form of a resolution at Dublin, demanding that this practice by English institutions be discontinued, and declaring the qualifications of the physicians of the different divisions of the island to be equal. This produced excited discussion, but, the meeting being held on Irish territory, the resolution was carried through with a cheer. The reports of the various committees on legislation might be thus summed up: "We have done everything possible, and have accomplished nothing." Their efforts in the direction of legislation seem to be about as persistent and fruitless as with us. The endeavors on the part of the committee to secure legal control of the habitual drunkard were especially worthy of notice. The finances of the Association were reported in a solid condition The British Medical Association now owns its own property on the Strand in London, where are located the permanent headquarters and the office of the journal. The annual income exceeds the expenditures, and a nice remainder is left each year. The membership of the Association includes the members of all the auxiliary societies, and numbers about 12,000, 1200 of whom were present at the Dublin meeting.

Dr. McKee then said: "My time was almost exclusively spent in the Section on Obstetrics and Gynecology, but there was quite an amount of good scientific work done in all the sections. The Section on Obstetrics and Gynecology was highly favored in hearing two papers by Dr. Apostoli, of Paris, on his method of treating fibroid tumors of the uterus and endometritis. He gave a demonstration in the Rotunda Lying-in Hospital, of his method of applying electricity in the treatment of diseases of the uterus. Dr. A. V. Macan, Master of the Rotunda, was President of the section, and, in his fine address, told of the practices and successes in the obstetric art in the long career of this old and famous institution. He made a most excellent executive officer, cutting off the long-winded talker and drawing out the man whose erudition was only equaled by his modesty. Under his command, little time was lost and much work was accomplished. In calling for discussion, he would say: 'Has any gentleman anything *new* to say, *not* simply anything to say?'

"The meeting was accompanied by a grand succession of social entertainments. We were dined and wined, given suppers, garden-parties, soirées, receptions, balls, and sermons. The British far excel us in hospitalities to the visiting medical brethren within their gates. The Ohio State Medical Society may feel itself honored by the manner in which its representative was received by the British Medical Association. My visit was much more pleasant than had I gone there without my papers as delegate from this Society."

Election of Officers.

The election of officers resulted thus: *President*, P. S. Conner, M.D., LL.D., Cincinnati; *First Vice-President*, Dr. D. Halderman, of Columbus; *Second Vice-President*, Dr. B. M. Ricketts, of Cincinnati; *Third Vice-President*, Dr. A. H. Brundage, of Xenia; *Fourth Vice-President*, Dr. H. M. Brown, of Hillsborough; *Secre-*

tary, Dr. G. Collamore, Toledo; *Assistant Secretary*, Dr. E. C. Brush, Zanesville; *Treasurer and Librarian*, Dr. T. W. Jones, of Columbus. Various committees were elected. So much time was consumed in the elections that it was decided, on motion of Dr. Dudley P. Allen, of Cleveland, that in the future the selection of all officers, except the President, will be left to a committee on nominations, consisting of five members.

The number of invitations given made the selection of a place of meeting for next year rather difficult. Put-in-Bay, Columbus, Youngstown, Canton, and Delaware were presented and their respective merits urged by their champions. After much debate, the selection fell to Youngstown.

The Society was entertained by receptions at the residences of Dr. Starling Loving, Dr. J. W. Hamilton, Dr. W. D. Hamilton, and at the Central Ohio Lunatic Asylum, all of which were very enjoyable.

Dr. Dudley P. Allen, of Cleveland, and Dr. A. W. Ridenour, of Massilon, each read papers upon the Radical Cure of Hernia. The former presented two cases operated upon with successful result. Dr. Ridenour discussed the different varieties of hernia and the modes of reduction.

The experiments performed by Prof. Senn at the late meeting of the American Medical Association were repeated by Dr. R. Harvey Reed, of Mansfield. He injected hydrogen gas into the rectum of a dog, and ignited it as it passed from a tube inserted into the esophagus, thus demonstrating the fact that the ileo-cæcal valve is not impassable.

Dr. J. T. Whittaker, of Cincinnati, read a paper upon the

Therapy of Tuberculosis.

He commenced with the statement that five-sevenths of mankind suffer, at one time or other, with tuberculosis; that many have it in some form and recover is proved, he said, by post-mortems. One-seventh of the population of the globe die of one manifestation of this disease—tuberculosis pulmonum. On June 13, twelve persons died of consumption in Cincinnati; others of convulsions, meningitis, and different complaints really tubercular. Koch announced his discovery six years ago, and to-day it remains undisputed. Practical results, he admits, have not yet been obtained from it, however, and pulmonary tuberculosis remains as intractable as ever; but no treatment of this disease is scientific which does not refer to the bacillus. Koch has made the discovery, and it is the duty of clinicians to cure the disease on the basis of the discovery.

The good effects of high altitudes are probably due to increased lung-exercise, as it requires three times as much exercise to breathe at such heights as at the sea-level. Fresh-air gymnastics, as Sydenham said of horseback-riding, bears the bell. Cod-liver oil has done more for consumption than all other therapeutic remedies put together. The food of the highest force-value is alcohol. Alcohol, fresh air, and cod-liver oil are no new remedies in the therapy of tuberculosis.

Boiling for twenty minutes, or corrosive sublimate 1–1000, is necessary to destroy the bacillus of tubercle. Dr. Whittaker then said: "After experimenting for a year, I have reached the conclusion that no inhalation will kill the bacillus, and have entirely abandoned the trial. I have also tried corrosive sublimate by inhalation and by parenchymatous injection without success. I have had a year's experience with creasote, increasing it a drop a day until 25 drops, or even 40, were given daily. Guaiacol has no superiority over creasote. Aline sulphide, the essential principle of garlic, caused more speedy results, but the scent of the garlic was well-nigh unbearable." Dr. Whittaker said he had been experimenting with the oil of black mustard for a month past and had seen some marked improvements, but he thought the time was too short to permit him to speak with authority of this remedy. He hoped some of the gentlemen present would take up the subject and assist him.

Dr. Herrick, of Cleveland, said he did not believe in the germ-theory of tuberculosis; he thought the bacillus was not the cause, but the result, of the disease. The disease is only a disturbed nutrition; we always find an antecedent disturbance of nutrition in tuberculosis. He took issue with Dr. Whittaker as to his ideas in regard to alcohol as a heat-producer in the body.

Dr. W. J. Scott, of Cleveland, said he did not believe that healthy people are liable to contract tuberculosis.

Dr. J. T. Whittaker said: "Dr. Herrick must ignore all cultivation experiments. We can introduce the bacillus of tubercle into the body of a healthy animal and produce tuberculosis. Dyspepsia does occur frequently—in fact, in about one-third of all cases; 90 per cent. show ulcer of the intestinal canal. It is very questionable if tuberculosis is ever inherited. This bacillus is a

stumbling-block to the theory of inheritance. It is a vegetable seed. How can an animal tissue cause a vegetable seed? I think the time is not more than a decade distant when we will throw away the stethoscope and make our diagnosis of tuberculosis by an examination of the sputa alone. It must be made a crime not to disinfect the sputa. A man might as well walk the street, firing a loaded revolver, as expectorating tuberculous sputa right and left."

Dr. P. S. Conner, of Cincinnati, read a paper on

Malpractice Suits.

He was especially qualified to speak, having just passed through a suit. He said that, in the great majority of instances, malpractice suits are brought with the intention to rob, a species of blackmail. So long as rascally lawyers and scoundrelly doctors exist, so long also, he said, will malpractice suits have an existence. There seems to be an epidemic of them in Ohio at present. He then read a bill which is in force in the State of New York to protect physicians, surgeons, dentists, and others from speculative malpractice suits. This bill requires that bonds be given equal to twice the amount claimed as damages, in case the suit be lost or dismissed. With such a law as this on our statute-books, he thought we would have all that was needed. Persons will then, he said, be careful how they bring or encourage malpractice suits. Dr. Conner then presented a resolution, which was adopted, requesting that a special committee be appointed to present to the Legislature, at its next session, a bill similar to the one now on the statute-books of New York.

Dr. W. J. Scott, of Cleveland, reported

Four Cases of Diabetes Mellitus.

They were treated by the diet method recommended by Dr. Pavy at the last International Medical Congress; they were not cured, however.

Dr. B. Merrill Ricketts, of Cincinnati, read a paper on the

Treatment of Acne.

He had found massage sometimes beneficial, especially when it was accompanied with Turkish baths. Iron, arsenic, and strychnia, he said, are serviceable as tonics. One-eighth grain of arsenious acid given with the elixir of gentian, tr. ferri chloridi with a few drops of hydrochloric acid after each meal, gradually increased until one-half or three-quarters grain is taken daily, is by far the best treatment. As an external application, a stimulating paste, composed of ichthyol and mollin, should be applied after all sebaceous matter has been removed with an application of hot water. Resorcin with sub-nitrate of bismuth, zinc oxide and mollin, or lanolin, is also good.

Dr. Wm. T. Corlett, of Cleveland, read a paper on

Diseases of the Skin, due to Defective Alimentation.

He reported a number of cases and described the treatment.

Dr. H. M. Brown, of Hillsborough, read a paper on

Painless Treatment of Rectal Disorders.

His treatment consisted largely in the use of cocaine. His investigations had proved beneficial alike to his patients and himself.

Dr. H. J. Herrick, of Cleveland, read a paper on the

Contagiousness of Disease.

He did not believe much in the germ-theory of disease, especially as it affects consumption.

LEHIGH VALLEY MEDICAL ASSOCIATION.

Eighth Annual Meeting.

The Lehigh Valley Medical Association held its eighth annual session at Paxinosa Inn, near Easton, Pa., on Wednesday, August 15. About seventy physicians, members, with their invited guests, assembled in the parlor of the inn, while their wives and daughters were enjoying the views from the porches or rambling through the chestnut groves near by.

Dr. W. B. Erdman, the retiring President, delivered the President's Address, selecting as his subject "The Character and Objects of the Medical Profession." This he presented largely from the negative side. After speaking of the greatness and dignity of medical practice, he said: "He who enters this profession from merely sordid motives, having failed to recognize the principles on which permanent success therein is founded, will either miss the very end he has aimed at and fall by the wayside, or, abandoning all pretense of regular and honorable conduct in his practice, will be swallowed by the maelstrom of quackery." With this introduction, he gave a study of the natural history of quackery, illustrating with very apt historical allusions. The reason of

success of quackery is due to a want of knowledge on the part of the people, and the influence of novelty and mystery which the "isms" suggest. By thoroughness of preparation, honesty of purpose, and integrity of character, the true physician should aid in dispelling this abnormal condition.

The annual address was delivered by Dr. T. J. Mays, of Philadelphia, upon "The Treatment of Lung Cavities." This topic was selected because of its frequent occurrence, and the prevailing opinion that the cavity is beyond the power of treatment. After giving a clear *résumé* of the pathology of the condition, he advanced to the therapeutical portion of the paper. The cardinal principles must be remembered, (1) that it, as well as the disease of which it forms a part, is inherently a process of necrosis, of mortification; (2) that not only its size, but its existence, depends on the degree of local and constitutional resistance. As a rule, a patient with a quiescent cavity is more desirable for treatment than one who has an infiltrated lung. The special indications for treatment were enumerated, as (1) fever, (2) anorexia, (3) wasting, (4) harassing cough and expectoration, (5) loss of sleep, (6) diarrhœa, (7) hæmoptysis. For the fever, antipyrine was given the first place. Ichthyol, administered through a respirator in a strength of twenty-five per cent. aqueous solution, exercises a beneficial effect on the fever by its effect on the inflammatory process in the lung Alimentation is all-important, but here the cook is sometimes of more importance than the doctor or nurse in so preparing the food that it will be appetizing. The morning cough will continue until the cavity is emptied. A position on the hands and knees, with the head lowered, will often hasten this. For hæmoptysis, the use of the fluid extracts of hamamelis and geranium—one part of the former to three of the latter, in teaspoonful doses every hour or two, or oftener if necessary—was especially commended. The last item of treatment mentioned was pulmonary gymnastics, which should be employed, and, if with proper precaution, benefit will result.

In the executive session, Dr. George N. Best, of Rosemont, N. J., was elected President. The Executive Board was authorized to arrange a meeting during the winter, to be devoted more especially to the discussion of medical subjects. (The Board afterward determined to hold a meeting in Allentown late in January.)

After adjournment, the Association joined the friends on the porches, they having had a pleasant social time enjoying the beautiful view which the erection of the inn had made accessible. Paxinosa Inn is situated on a hill north of Easton, some six hundred feet above the Delaware River, and affords an extensive view on all sides. The annual dinner of the Association was then served, and, although the members have grown very fastidious because of previous excellent dinners partaken of, all were pleased with the careful selection and proper preparation of the viands served; indeed, before departing, they were loud in their praise of the inn, as to its position, its appointments, its comforts, and its sanitary precautions.

PERISCOPE.

Pneumonia as a Contagious Disease.

In the *Archives générales de Médecine*, July, 1888, Dr. Netter concludes an elaborate paper on the contagiousness of pneumonia. He regards pneumonia as a transmissible contagious disease, and that the contagion owes its activity to specific pathogenic organisms, pneumococci, which multiply in the pneumonic foci and are discharged from the body by the different passages, but are especially abundant in the sputa. He thinks, moreover, that contagion is still possible long after the patient has recovered from the disease. The reasons for this belief are two: first, because the contagious matter resists desiccation, and can preserve its activity outside the human body on the surface of inert bodies to which it adheres; second, because the contagion is not destroyed in the patient after the termination of the pneumonia. Long after the latter—perhaps indefinitely—persons who have recovered still have in their mouths active pneumococci, and it is to the activity of the latter that he thinks we must attribute both the great frequency of relapses and the large number of persons belonging to one family who are often exposed to pneumonia.

Dr. Netter, however, does not believe that rigorous isolation is necessary in pneumonia. He would object to the parents of the patient passing the night in the same room with the sick one, and especially to their sleeping in the same bed. They should be informed, he says, of the necessity of leaving the room from time to time, and of the danger of using linen soiled by the patient.

In hospitals, he says, patients with pneumonia should not be placed in small rooms by themselves, for the contagion is only slightly diffusible. All the published cases

show that contagion has been especially observed in small ill-aired rooms. Patients suffering with typhoid fever, measles, acute diseases of the air-passages, nephritis, and diabetes ought not to be with patients suffering from pneumonia. Hospital life is recognized now as predisposing the most of these diseases to tuberculosis. Dr. Netter believes that this influence can act also in favoring the production of pneumonia.

Inasmuch as the sputum, if not the only, is at least the habitual, vehicle for the contagion, it should be disinfected. Corrosive sublimate has been found efficient for this purpose. He advises that the linen should be subjected to the same disinfecting process as is used for the linen coming from those affected with other contagious diseases. Disinfection of the mouths of patients with pneumonia should by no means be neglected.

Foreign Body in a Woman's Bladder simulating Stone.

At the meeting of the Obstetrical Society of Boston, April 14, 1888, Dr. C. M. Green reported a case of foreign body in a woman's bladder simulating stone. He said that the patient was a young woman of previous good health, who for some time had suffered with frequent and painful micturition. There was almost constant pain through the bladder, which was increased by motion, especially in riding or in walking on uneven surfaces, as in stepping from the sidewalk to a street-crossing. Occasionally particles of gravel were voided, and rarely, minute clots of blood. Examination of the bladder proved very difficult, as the urethra was exquisitely sensitive; but a silver female catheter was passed, and the urine thus obtained found to be alkaline and of strongly ammoniacal odor. On manipulation, the catheter was felt to pass over a gritty mass, which on subsequent bimanual examination appeared to be about the size of a hen's egg. No clink was elicited by the impact of the catheter, but, from the symptoms and other facts mentioned, a diagnosis was made of vesical calculus. After some preliminary treatment, the patient was etherized and a lithotrite passed into the bladder to crush the suspected stone. Repeated attempts failed to enable the operator to grasp the stone, for on closing the lithotrite it seemed to grasp only the bladder wall; finally the operation was abandoned. Thorough washing of the bladder, however, brought away much sand and several small pieces of calcareous substance, and it was decided to wash the bladder daily with a solution of boracic acid and await further developments, in the belief that what had been taken for a stone must be one or more masses of calcareous matter adhering to the bladder wall.

For four days the patient was much better, and daily washings continued to bring away gritty particles. The next day, however, the urine was very offensive and contained blood and mucus; the patient was unable to sleep, on account of pain and vesical tenesmus. It was then decided to dilate the urethra and explore the bladder with the finger. This being done, the suspected stone was found to consist of a soft rubber catheter, coiled up to the size of a hen's egg, and thickly coated with calcareous deposit. This had been caught in the lithotrite and gave the sensation of catching the bladder wall. No incontinence followed the dilatation of the urethra, and the patient made a very satisfactory recovery. She denied all knowledge as to how the catheter came to have been left in her bladder, and expressed great indignation that some doctor should have been so unskilful; but Dr. Green expresses the opinion that the catheter had been used either by herself or by an abortionist for the purpose of interrupting a supposed pregnancy, and had been ignorantly passed into the bladder and lost there.

In discussing Dr. Green's paper, Dr. Elliot spoke of a case in which, having dilated the urethra, he had found calcareous masses plastered over the bladder wall, and had been unable to remove them with the finger. He therefore crushed off the masses with the lithotrite, but had great difficulty in washing out the bladder. He finally found that the evacuator was clogged with pieces of twisted paper, which proved to be fragments of a paper lamplighter. The lamplighter had evidently been passed into the bladder by the patient, and had become the seat of calcareous deposit, and subsequently adhered to the bladder wall.

Dr. Elliot suggested that for purposes of digital examination the female bladder should be empty of urine, as the finger can then palpate the whole surface. In regard to the use of the lithotrite in such cases, he said, the instrument should be held in a perpendicular position, otherwise it hits the uterus.

In the case just mentioned, recovery was speedy and there was no incontinence; he had used, for dilating the urethra, Hank's dilators first, and subsequently the finger.—*Boston Med. and Surg. Journal*, July 12, 1888.

P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

A FOLLY WHICH IS ALMOST A CRIME.

In the reports which the daily papers give of a camp-meeting held recently near Philadelphia, we read that a certain person, only twenty years old, and known as the "boy missionary," was to be married, on August 15, to a girl of the same age, and soon after to proceed to Africa as a missionary. The boy missionary and his intended wife are both said to be small, and the bridegroom to be delicate. The marriage seems to have been approved by the boy's clerical superiors, and to have aroused no opposition whatever.

We cannot, however, permit the occasion to pass without notice. Medical men have a duty to perform to their fellow-men beyond that of trying to get them well when they are sick. It is quite as much their office to warn their fellow-men of danger to their health and lives, and, if need be, to endeavor to dissuade them from doing what is likely to lead to unfortunate physical results. The case of the boy missionary, therefore, suggests a decided remonstrance against an act of folly which, from the physician's standpoint, is almost a crime. It is bad enough for immature persons to be joined in wedlock; but it is worse when one of two such persons is so frail as to be spoken of as "delicate." Add to this the intention of going to such a country as Africa, and what can medical men think of the prospect? If these young enthusiasts do not lose their lives very soon, what can be expected as the result of their conjugal relations? If they have any progeny, how can this progeny be other than ill-developed and unable to maintain the struggle for existence? This is a question which will rise naturally in the mind of medical men, and which should have been considered by the advisers of this couple. For the young people themselves, we have only pity; but for those whose age should have given them greater wisdom, we have only condemnation. Unfortunately, they have some justification in custom and precedent; and, for this very reason, we seize the present occasion to sound a note of warning.

Unwise marriage is one of the most fruitful sources of deterioration of the human race. Were it not that material prosperity and a continually increasing knowledge of the conditions of health tend to improve the race in this country, we might well fear that our customs in regard to courtship and marriage would soon ruin it. It is for others to speak of the considerations of social and mental fitness for marriage: it is for us, as medical men, to instruct our fellow-men in regard to the conditions of physical fitness. That these conditions are not regarded, as a rule, the slightest observation shows; and the effects of this neglect are known to every practitioner of experience. When, therefore, so conspicuous an

illustration of this neglect is furnished as has provoked these remarks, we believe it is high time for medical men to protest against it, and to state plainly that, from their standpoint, it is a folly which is almost a crime.

MEDICAL EDUCATION.

It is one of the most hopeful signs of the present time that the subject of medical education is attracting a great deal of attention, and that in our own country there is an unmistakable desire to find out and put into operation the best methods for the development of intelligent and successful practitioners of the healing art. A large part of the time of our medical societies is spent nowadays in discussing the plans proposed or followed by different medical schools in educating their students, and the columns of the REPORTER have, of late, frequently borne witness to the zeal of those who are striving to secure the highest efficiency of the schools, and to our own sympathy with the object they have in view. It will be understood, therefore, that we regard with much interest every carefully-considered contribution to this discussion, and think it proper to bring the subject to the notice of our readers again and again.

One of the most important addresses on medical education which has appeared of late was delivered by Dr. Ely Van de Warker before the Section on Obstetrics at the last meeting of the American Medical Association, and is published in the *Journal of the Amer. Med. Association*, August 11, 1888. The title of this Address is "How Gynecology is Taught"; but the author considers much more than his title covers, and his address opens up questions which affect the whole subject of medical education in the United States.

It would be impossible here to indicate all the matters to which Dr. Van de Warker alludes; but we wish to add our endorsement to an objection which he raises against the tendency in some medical schools toward methods of education which are better theoretically than they are practically. Our own acquaintance with the methods of teaching followed in first-class medical schools does not lead us to share his idea that schools with graded courses of study exalt the text-book above the teacher; but we do believe with him that some of the best schools in the country are pursuing a course which tends to produce men who can pass brilliant examinations, rather than men who will be careful observers and shrewd thinkers. The disadvantages of the old seven-branch system of teaching need not be dwelt upon to justify the general opinion of its insufficiency for the requirements of the present day; but we believe that there will be a reaction from the sentiment which in our day would force all the schools in America to a standard of education which exacts so much of students as is indicated by the examination papers of schools like Harvard and the University of Pennsylvania. Such a standard we believe to be suited to only a very few schools, and utterly unsuited to the needs or conditions of most men who purpose entering upon the practice of medicine. Its fault, in our opinion, is that it attempts to cram into every head the wisdom of a whole faculty, and this in a space of time which is totally inadequate for any such purpose. Everyone who studied under the old seven-branch system knows how severe the strain was then upon the diligent student; and now, when the subjects of study are divided and multiplied until it is hard to say how many they are, the strain is well-nigh intolerable; beside this, some of the branches which were once only reasonably hard are pushed nowadays out of all proportion to the real needs of the student. Chemistry furnishes a good illustration of the fact. Once the student was expected to acquire a fair knowledge of physics and of general chemistry, but nowadays he is expected to fit himself to pass an examination which would make his father shudder,

and which would floor every one of his numerous examiners, except the professor of chemistry. So in physiology: the study of organs and tissues, of functions and disturbances, which sufficed for starting the teachers who now oppress him, was as nothing to the burden imposed by the modern experimental physiology, with its indescribable machinery and its wearisome details.

Let it not be supposed that we deprecate thorough study in chemistry or physiology, or that we fail to appreciate the advantage of a refined knowledge of both. But it seems to us that it is a mistake to push a whole class of medical students as if each member of it meant to be a specialist in these branches. This mistake appears the more striking when we look at the way in which anatomy is treated nowadays. The study of anatomy, in graded schools, is usually regarded as ended at the end of the second year. For two years the student gets what he can of anatomy, fighting hard against the exactions of chemistry, physiology, and materia medica, and then he is driven on the so-called practical branches for another year, to the utter exclusion of a branch which ought to be studied as long as he is within college walls.

Then, when we regard the question of modern medical education, and the strain upon students, we must consider the demands of the specialists. The teachers of gynecology, of ophthalmology, of otology, of dermatology, of pædiatrics, of orthopædics, and so on, feel very naturally the importance of giving medical men some preparation for practicing in each of their departments; and all of them are pressing to have their special branches made a part of this regular curriculum. But will human endurance bear the strain? Already the cry comes from some advocates of higher education that we must have an obligatory four-years' course. But it is easy to see that four years will soon be too short a time in which to cover the enlarged field of study, and so may six or ten years be, after a while.

Now, it is easier to make objections than to propose remedies; and we can see the disadvantages of trying to secure too much for and from students of medicine more clearly than we can the way to give them just enough of education to make them useful and contented men. But we believe that the majority of schools which give the degree of doctor of medicine will have to come to a standard which recognizes the fact that there is a limit to the possibilities of the average student, and that the duty of the schools is to give their students a reasonably good start, leaving them to perfect themselves by post-graduate and voluntary study, as their opportunities permit and the conditions under which they are to practice may demand.

How this shall be done is a very large question—too large to be discussed now. What we have said is meant rather to suggest a line of thought than to direct it. We all wish to reach the highest standard of medical education which is attainable; but it is worth while to consider seriously whether or not some of the energy nowadays devoted to securing a higher education is not misdirected and likely to do harm to the good cause in which it is enlisted.

THE RELATION OF PTOMAINES TO POISONOUS FOOD AND TO INFECTIOUS DISEASES.

Everyone who has endeavored to keep abreast of the wonderful advances made in the different departments of medicine within the last two decades has doubtless found his powers of memory and observation severely taxed. The modern system of specialisms, though doubtless fraught with some evils, has at least this advantage —that it enables its followers, by devoting exclusive attention to a single line of research, the more thoroughly to master their subject, and thus elicit new and important facts, which otherwise might escape notice.

We have been forcibly reminded of the

above truth by reference to the modern discovery of the ptomaines, and their elucidation by a number of distinguished scientists, among whom we are glad to place our countryman, Professor Vaughan, of the University of Michigan, the discoverer of one of the most important of these interesting bodies.

We have thought that our readers, some of whom may not have had the opportunity to examine this important subject, would be pleased to have a *résumé* of what appears to have been determined in connection with it.

As is well known, *ptomaines* (from πτῶμα, a dead body) are chemical basic substances, formed during the putrefaction of organic matters—chiefly animal. On account of their resemblance in many respects, both in their chemical and physiological characters, to the vegetable alkaloids, they have been also named *putrefactive alkaloids*.

The poisonous nature of putrid flesh, of certain varieties of mussels, sausages, cheese, and canned articles of food, etc., has long been a matter of experience. These substances, when eaten, frequently occasion most violent, and often fatal, results, resembling the effects of the acrid narcotic poisons —such as vomiting and purging, severe muscular pains, disturbed breathing, headache, stupor, delirium, dilated pupils, difficulty of swallowing, great prostration, convulsions, coma, and death. We read almost daily in the newspapers of such cases occurring after partaking of what were thought to be very innocent articles of food —such as milk, ice-cream, cream-puffs, canned provisions, etc. In these instances, as the symptoms usually resemble, in many respects, those of the ordinary mineral poisons, the search after arsenic, lead, tin, or copper, of course, proves unavailing, because of the absence of all of these last-named substances; the whole trouble has been caused by the presence of one or more of the noxious ptomaines, generated in the subtle process of the decomposition, or spoiling, of the material that had unsuspiciously been used as food.

It is clearly understood that all these noxious articles of food produce their poisonous actions exclusively through the ptomaines, which are true chemical poisons, as much so as morphine, strychnine, atropine, and other recognized poisonous alkaloids. True it is that the putrefaction is the result of bacterial agency; but it has been distinctly proved that the peculiar symptoms are not due to the absorption of the bacilli into the blood, as was once supposed, nor are they dependent on the direct agency of these micro-organisms on any of the organs or tissues of the body, but on the ptomaines resulting from the action of these bacteria upon the highly-organized material. The kind of ptomaine produced will depend on (1) the specific bacterium engaged in its formation; (2) the stage of putrefaction, ptomaines being transition-products, rapidly undergoing transformation; (3) external conditions, as temperature, supply of oxygen, etc. Although many of these products are poisonous, as just mentioned, the majority of them are innocuous.

What is of special interest to the toxicologist in this relation is the curious fact that these poisonous ptomaines bear a very close resemblance, both in their chemical and physiological behavior, to the well-known vegetable alkaloids. For example, several bodies have been isolated from decomposing human flesh, and one from decomposed corn-meal, that gave crystalline precipitates with certain chemical reagents, and yield also the usual color-test of strychnine; some of these also caused tetanic spasms when injected into frogs. Another ptomaine bears some resemblance to morphine, reducing iodic acid, but failing in other tests. Two volatile oily ptomaines have been extracted by different chemists from various kinds of animal putrefactive matters, bearing a considerable likeness to the volatile vegetable alkaloids, nicotine and coniine. And there are still others which exhibit many of the

properties of the well-known mydriatic alkaloids, atropine, duboisine, and hyoscyamine, causing, when injected into animals, dilatation of the pupil, increased action of the heart, and paralysis of the muscles of the intestines. Besides the above, other putrefactive alkaloids might be mentioned, such as bodies resembling digitaline, colchicine, veratrine, etc. Indeed, there would seem to be no limit to the number and variety of these singular compounds, since they are so very unstable and prone to chemical transformations.

The important practical medico-legal inference to be deduced from the foregoing facts is the danger of mistaking one of these ptomaines for one of the vegetable alkaloids in a case of alleged poisoning by the latter. As we have seen, there is quite a remarkable resemblance between the two, both in their chemical reactions and in their physiological properties. Before the discovery of these ptomaines, there was, comparatively speaking, no difficulty for the toxicologist to detect most of the well-known alkaloidal poisons; now, however, there must always be more or less uncertainty in the result of such an investigation, especially if made on a putrefied corpse. At all events, it will behoove the expert to exercise the greater caution in his examination, especially in a capital case, so as to be able *positively* to exclude the presence of any of these interfering ptomaines in his ultimate results, on which he founds his opinion as to the existence or non-existence of the alleged lethal poison in the body of the deceased. And it is very easy to see what a powerful weapon this *doctrine of the ptomaines* furnishes to the skillful counsel for the defense in a criminal trial for alkaloidal poisoning, and how likely he will be to use it before the court and jury to confuse and embarrass, if not completely to break down, the testimony of the experts for the prosecution. But, fortunately for the cause of justice, here as elsewhere truth "will prevail." The resemblance between the ptomaines and alkaloids, although strong, does not amount to an absolute identity. There are certain special points of distinction between the two substances fully appreciated by the skilled toxicologist, which, if he exercise sufficient caution, will enable him to make a satisfactory diagnosis. These points of difference we are not able at present further to notice. They will be found, however, in most of the recent monographs on this subject.

One other fact here deserves attention, namely, that the simultaneous presence of one or more of these ptomaines with one of the vegetable alkaloids, in a dead body, will sometimes have the effect of partially or completely concealing the usual characteristic chemical tests for the last-named poisons. This circumstance may satisfactorily explain the cause of the occasional failure to discover an alkaloidal poison in the dead body.

The relation of ptomaines to infectious diseases opens up a most interesting field for discussion, but our limits only permit a hasty glance at some of the more prominent points.

The bacterial origin of infectious diseases is now almost universally admitted; indeed, the results obtained by following out rigidly the rules laid down by Koch would seem to leave no doubt on this point in a few special diseases, at least. As might be expected, different theories have been broached to explain how these little germs produce the disease after they have gained an entrance into the system. The oldest of these theories referred the cause to the deoxidation of the blood through the direct agency of the bacilli, which were said to be present in immense numbers in that fluid. Another assigned it to the accumulation of these bacilli in the blood-vessels, acting mechanically like emboli, and interfering with the circulation of important organs. Still another supposition was that the micro-organisms destroyed the integrity of the blood-corpuscles, and thus devitalized the blood.

But all these blood-theories have been disproved by numerous investigators, and are now abandoned; and they have given place to what may be termed the chemical theory, which may be briefly formulated thus: Each specific bacillus, acting upon the complex organic material (as in the case of putrefaction), produces therefrom poisonous ptomaines, which are absorbed into the circulation just as ordinary poisons, and produce their peculiar impression upon the centres of life—the heart, lungs, brain, and great nerve-ganglia. It will now be understood that each infectious disease has its own specific pathogenic micro-organism, which, having gained admittance into the body under favorable conditions, grows and multiplies, and, in so doing, elaborates a special ptomaine—a chemical poison—which produces its characteristic effects.

That this is not mere hypothesis is shown by numerous experiments, in which, by pure culture of the different specific bacilli, the various corresponding ptomaines were subsequently procured by chemical processes; and, when these ptomaines were injected into the lower animals, many (though not all) of the symptoms peculiar to the specific disease were exhibited. This has been proved in the case of bacteria of anthrax, tetanus, and typhoid fever, in each of which the pathogenic ptomaine has been extracted, and shown to be active in the subsequent production of the characteristic symptoms in a living animal. It has not yet been verified in all infectious diseases, though the probabilities are in favor of its general application.

Much more might readily be written upon this very interesting subject, did our time and space justify it; but enough has been said to stimulate our readers to a farther pursuit in this line of investigation. It is especially suggestive to the toxicologist and the pathologist, and it should not be the less so to the therapeutist, as it opens up an inviting opportunity for the exhibition of antidotal or antagonistic remedies.

ANTISEPTIC MIDWIFERY IN PRIVATE PRACTICE.

The theory of Semmelweiss, of the nature of puerperal septicæmia, with its modern development and deductions, has obtained general recognition and acceptance The question whether or not antisepsis shall be adopted in private obstetric practice presents itself to the practitioner from several points of view. In the past, sepsis has been much more prevalent and fatal in hospital than in private practice. This is by no means so true at present. Antiseptic midwifery has done much to reduce this disparity; indeed, it is more than probable that puerperal septicæmia is more fatal to-day in private practice than in well-conducted hospitals. If this is true, the practitioner can no longer ignore this question. His patient's interests demand that he shall adopt as perfect a system of antisepsis as circumstances will permit. Practical men are aware that it is impossible to adopt a method that can be carried out in all cases. But it is always possible to practice personal disinfection, and, except among the ignorant, to see that the nurse does the same, before touching the genitals. These simple measures, in addition to the methods of cleanliness practiced among the better classes, would reduce very greatly the occurrence of sepsis. It is usually possible to do more than this, and a simple yet efficient method of antisepsis should be adopted. We know of no systematic method better adapted to use in private practice than that employed at the Philadelphia Lying-in Charity (Reporter, March 31, 1888). We do not believe that the most earnest efforts on the part of the physician will always succeed in preventing sepsis in private practice; nor is it likely that relatively as beneficent results will be obtained in private as in hospital practice, for the reason that neither the patient nor her environment is so absolutely under his control.

Our conservative views are not shared by all, and, owing to the radical position held

by some, this subject has recently assumed importance from a medico-legal aspect. We doubt not that in the near future some practitioner who has been so unfortunate as to lose a patient from puerperal septicæmia will be sued for damages upon the plea of malpractice. In the discussion upon Dr. Adams's paper on "Antiseptic Midwifery," read before the Essex North Dist. Med. Society (*Boston Med. and Surg. Journ.*, March 1, 1888), Prof. Wm. L. Richardson, of the Boston Lying-in Hospital, expressed himself very forcibly on this subject. He considers peritonitis, milk-fever, swelled legs, mammary abscess, sore nipples, pneumonia, or an elevation of temperature above 100° F., during the puerperium, as evidences of septicæmia; and that the physician is responsible if death occurs from any of these causes. He thinks that, should a case go to court, "it will go hard with a physician unless he can succeed in shifting the responsibility on to the nurse." This opinion is partly based on the results of antiseptic midwifery in the Boston Lying-in Hospital, under which there have been nine hundred deliveries without a death from sepsis, while before the antiseptic era the mortality was always high, and it was sometimes necessary to close the hospital. Dr. Jaggard expressed similar views in the discussion of Dr. Hoag's paper on "The Importance of Abdominal Palpation in Obstetrical Diagnosis," read before the Gynecological Society of Chicago (*Amer. Journ. Obstet.*, p. 1210 *et seq.*, Nov., 1887). This subject was also discussed before the Chicago Medico-Legal Society, March 3, 1888.

At this time, it is scarcely necessary to do more than allude to the importance of antiseptic methods to the patient. The present status of this question is of peculiar interest to the physician. He must use antiseptic methods not only for conscience' sake, should he lose a patient from puerperal septicæmia, but that he may be able to justify himself in court, in case of a suit for malpractice.

NEW YORK QUARANTINE.

The defects of the New York Quarantine Station are once more attracting the notice of the country. The last demonstration of the way in which it is managed consisted in the death of two men from yellow fever, in a Cuban vessel, while it was lying unsuspected at a dock in Brooklyn, after it had been passed through the hands of the Health Officer.

Such an occurrence as this adds renewed force to what we have before said of the necessity that the General Government shall take charge of the quarantine of the whole coast, and not leave it to each State to manage or neglect, as may happen. When the most important port in the United States gets itself into notoriety for the carelessness with which it guards against the invasion of disease by means of ships, it is high time that the regulation of the quarantine of that port, at least, should be taken out of its hands and confided to more faithful or more competent ones.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

CHEMICAL PROBLEMS. By J. P. Grabfield, Ph.D., and P. S. Burns, B.S., Massachusetts Institute of Technology, Boston, Mass. Small 8vo, pp. 87. Boston: D. C. Heath & Co., 1888.

This little book contains no preface and no explanation why it was prepared. It is to be inferred, however, that it was intended to be used as a guide to work in chemistry in the Massachusetts Institute of Technology and elsewhere, if deemed suitable to instructors in this branch of science. Those who need such works will judge its merits for themselves. To us, it appears to be a capital book, and well suited to furnish an outline of a course of study in chemistry for those who have already become familiar with its elementary details. It is not a book for neophytes, by a great deal, and it makes one who learned what he did of chemistry in the old-fashioned way tremble to read the questions contained in the examination-papers here published.

Happily for those who shall use this book, it is admirably written; the statements made are clear and succinct, and the plan pursued is logical and interesting. We have no doubt that the book will serve a useful purpose, and contribute to the reputation of its authors. Its mechanical execution is very creditable to the publishers—paper, printing, and binding being excellent

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

The Results of Laparotomy for Acute Intestinal Obstruction. By B. Farquhar Curtis, M.D., New York. From the *Transactions of the Med. Soc. of the State of New York* for 1888. 24 pages.

Are Dipsomania, Kleptomania, Pyromania, Etc., Valid Forms of Mental Disease? By Orpheus Everts, M.D., Cincinnati. 8 pages.

Annual Report of the Superintendent of the Cincinnati Sanitarium for the Year Ending November 30, 1887.

The Trituration of Alkaloids. By Edward Pynchon, M.D., Chicago. From the *Western Medical Reporter*, May, 1888. 8 pages.

Etiology of Typhoid Fever, as Observed in Country Practice. By L. N. Davis, M.D., Farmland, Ind. From the *Journal of the Amer. Med. Association*, April 21, 1888. 8 pages.

—Dr. Curtis has analyzed and studied the results of laparotomy performed for the relief of intestinal obstruction in 328 cases, and gives in his pamphlet the details of his analysis and the conclusions to which his study has led him. These conclusions are identical with those of other surgeons who have given much attention to the subject, namely, that the high death-rate—58 per cent.—is attributable largely to delay in operating, and the consequent bad condition of the patients; and that early and rapid operations would probably reduce the death-rate materially.

We can strongly recommend his paper to the consideration of our readers, and especially to those who do not practice surgery, since the responsibility for the result of an acute obstruction of the bowels usually rests with them.

In conclusion, it is pleasant to note the admirable literary style of this pamphlet, in which we have noticed only one thing to which we would take exception: the use of the pronoun "we" for "I."

—In opening a discussion on this question, before the Association of Medical Superintendents of American Institutions for the Insane, at Detroit, in June, 1887, Dr. Everts stated his opinion that an uncontrollable impulse to use stimulants, to steal, to burn, etc., does not develop independently of other evidences of insanity. From the observations of an extensive experience, and a purely scientific study of the subject, he believes that these morbid tendencies are usually associated with other evidences of perverted mental action, which leave no doubt as to the diagnosis; and that, when they are not so associated, great care should be exercised in classifying them.

This view appears to us to be entirely sound, and we believe that a proper appreciation of it, as explained by Dr. Everts, would be of great value in correcting a tendency, which was strikingly exemplified in the late Dr. Beard, to confuse the study of insanity by the use of terms which are misleading to those who are not aware of their proper restrictions.

—In this report Dr. Everts states that, out of two hundred and forty-four patients treated during the year, ninety-five were discharged cured, forty-two improved, and thirty-two unimproved; while six died, and sixty-nine remained under treatment. This interesting statement is followed up by further statistics, and by explanations which bear unusual marks of candor and courage. As a whole, the report is exceedingly creditable to the management of this institution, and the superintendent may well be congratulated upon it.

—Dr. Pynchon is a firm believer in the advantage of preferring the use of alkaloids to that of crude drugs in the treatment of disease, partly on the score of scientific exactness, and partly because it facilitates the dispensing of drugs directly by physicians instead of calling in the pharmacist as an intermediary between him and the patient. In his pamphlet, he states very forcibly the reasons which lead him to his belief, and proposes the plan of triturating various alkaloids with sugar-of-milk in such proportions that three grains of the mass shall contain an average adult dose. His plan is similar to that adopted by certain manufacturing chemists, and has much to commend it. Even more might be said than he has said in its favor; but he says enough to show that it deserves the careful attention of medical men, and especially of those who practice in small towns and rural districts.

—Dr. Davis, in this pamphlet, makes a very valuable contribution to the study of the etiology of typhoid fever. It is true, he raises questions to which he can give no answer; but he does give a very clear and intelligent description of the circumstances of a series of connected cases of typhoid fever, which seem to exclude a factor to which the greatest importance is usually attributed, and to emphasize the danger of another which is generally regarded as of less moment. Dr. Davis is evidently not carried away by the germ-theory of the origin of typhoid fever, and but little disposed to the short and easy way of accounting for its occurrence which too many medical men adopt.

We call especial attention to his paper, because it may serve as a model to many men whose opportunities of observation are large, but whose inclination to write is small. Such carefully studied cases as he has put on record in this paper are of the greatest value, and we wish there were more of them.

Literary Notes.

The magazine called *Woman* has passed into its second volume, with steady improvement in its literary contents. The number for June contains a very good paper by Charles Richards Dodge, entitled "Hints on Physical Culture for Our Girls," well illustrated, and calculated to be useful. Another interesting feature of this number, to which attention may be called, is the department called "Helps and Hints for Mothers." The whole is full of instruction and entertainment. Some of the advertisements will not be approved by medical men, but the inside pages are admirable.

The name of the *Canada Medical and Surgical Journal* has been *changed* to the *Montreal Medical Journal*. It has been enlarged in size from sixty-four to eighty pages, and the subscription reduced to $2.00 per annum.

Dr. Matthew Woods's book, descriptive of the art and literary centres of the Old World, from London to Rome, by way of the Rhine, with incidents by the way, is now ready for the press, awaiting only the work of the illustrators.

CORRESPONDENCE.

Management of the New-Born Child.

TO THE EDITOR.

Sir: Having read with interest the article from the pen of Dr. Ady in the REPORTER of July 28, 1888, and knowing that nothing is more gratifying to a writer than friendly criticism, I will devote a few thoughts to the article in question. Dr. Ady is not alone in his notion that he has peculiar ideas about the management of the new-born infant; careful reading of his article would lead anyone to the same opinion. At first sight the discarding of a woolen for a *canton* flannel slip (for canton, not cotton, is evidently meant) seems plausible, were it not that hundreds of years of experience bear testimony that wool warms and stimulates the newly-born in various ways, not the least important of which is the very irritation of which Dr. Ady complains.

I personally know of many robust young men and women, who to my personal knowledge kicked their toes for the first time against the woolen petticoat. *Light* dressing is certainly commendable, and his custom as to diaper and slip, depending on other wraps for warmth, is a good one, excepting the want of a band, of which more anon. His theory as regards the cord is not so good. If there is danger of blood oozing, which I doubt, would it not be much better to leave enough cord to tie again in case of such accident? Why not follow nature's plan, and leave enough cord to contract from exposure to the air, and thus prevent hemorrhage? Sepsis, as well as hemorrhage, is at a minimum. I have in my mind a careful old gentleman, dead now, who, in a country practice of 22 years, tied cords in 1140 cases, always 3 or 4 inches from the body, enclosing them in a greased cloth, never having had any trouble with the cord in that time. In my own case, I have never had either hemorrhage from the cord after tying it, or ulceration, but once, and that in a scrofulous child.

Dr. Ady's habit of not binding the abdomen has more of barbarism in it than the use of the belly-band has. The laparotomist teaches that the abdomen must be steadied by a bandage after any disturbance has been made of its contents. At the umbilicus there is pregnant cause for trouble, unless it is held in quietude by a bandage. Dr. Ady will admit the neat figure of our own Indian tribes who bind the children, abdomen and all, in infancy, while the pot-bellied native African, who runs like a partridge almost from birth, may be a sample of the doctor's enlightenment. In his first fifteen years, he lost two from bleeding at the cord, several from hernia, but he does not state the kind. Having become wiser, he discards bandages, woolen slips, and ligatures, and comes up smiling with a bare umbilical rupture in 20 years. So in 35 years he has 2 dead babies from hemorrhage, one umbilical rupture, several other ruptures, and nothing else. This is a good showing; but how many physicians with belly-band, old fashioned ligature, and comfortable woolen clothing can make just as good if not a better showing? Their name is Legion. No, Brother Ady, you must give better reasons why the baby should not be kept warm, why the cord should not be tied a few inches from the abdomen, and lastly, why its abdomen should not be supported until the cord has dropped off, the umbilicus healed, and the abdominal parietes accustomed to their changed relations.

Yours truly,

JAMES BATES, M.D.

Alliance, O.,
August 13, 1888.

More About Snake-Bite.

TO THE EDITOR.

Sir: Dr. S. A. Kemp, of Callicoon Depot, N. Y., is a good doctor, but very bashful. He has called my attention to a case, in his practice, of snake-bite cured by poultices of indigo and salt to the wound, together with the internal use of the leaves of the blue violet (*V. sagittata*), and he asks me to report this to you, because he dreads to approach the editorial throne. I take pleasure in doing so. The remedy is an old one, and may, doubtless, be good in certain cases; but I know it to have failed in our own State. Apropos of the subject, the letter from Dr. Milner, in the REPORTER which contained mine, was curious, as exactly reversing the opinion held by myself. Now, with all due deference to the doctor, I differ from his view, holding that the *acidity* of the virus of serpents, which he dreads, is not the toxic principle; hence alkalies, *per se*, are useless. The venom is an *arterial and nerve depressant*, and we require, therefore, a *stimulant* as an antidote. We administer freely nitro-muriatic acid with impunity, although it is more than a hundred times more acid than snake-virus. It does not, however, contain any special toxic principle; and I may say, in passing, that a specimen shown me of the isolated

crystal, stated to be the poison itself from the crotalidæ, was not acid in reaction; it was deemed an alkaloid. Permanganate of potassium is not strongly alkaline, neither is bromine as found in Bibron's antidote. Aromatic spirits of ammonia is too fugacious, and it also is not a violent alkali. Deaths from snake-bite are invariably the result of profound depression, not paralytic in effect. Dr. Milner is right in giving digitalis, but where his emetic comes in as eliminating or modifying a poison injected directly into the circulation goes beyond my comprehension.

I do not see the force of his analogy between strychnia and serpent-venom, nor the necessity for its introduction. The dose of strychnia administered by a physician is known, but the snake don't invite confidence; he gives the largest available quantity, and leaves no memoranda. We must, so to speak, feel our way. Any poison must be neutralized instantly when presented through a wound at the point of entrance. Once distributed through the circulation, we cannot saturate the blood-mass with specific antidotes; as, for example, alkali *versus* acid, or *vice versâ*. We must, then, combat the *effect* of the poison on the blood, the nervous system, the respiration, etc., as indications demand. Fatal snake-bites are comparatively rare, but experience has overwhelmingly shown that strong and prompt stimulation is demanded and is uniformly successful, whilst chemical experiments frequently fail. Indigo has, I know, experimentally been useful, but it was instantly applied. So have many other agents. When we have to deal with an absorbed poison, fully active, then we must treat upon foundation principles. The mild acid in snake-venom does not appear to be the lethal agent, hence we must look out for not only alkalinity (which is perfectly proper and can do no harm in moderation), but aim to reinforce the vital power during the period of prostration by such agents as we know will tide the patient over. The virus liquefies the blood strongly in fatal cases. Be it remembered that alkalies have the same effect in large doses or when long continued.

Yours truly,

W. R. D. Blackwood, M.D.

Philadelphia,
August 7, 1888.

—In October, 1888, an Italian Congress of Hydrology and Climatology will assemble at Bologna, under the presidency of Professor Murri.

Notes and Comments.

American Dentists in London.

A cable-dispatch to the *N. Y. Evening Post*, August 15, 1888, says that the proceedings against Drs. Huntley and Coe, two American dentists practicing in London, bring to light a curious hardship of certain Americans belonging to their profession. Until a few years ago, anybody could practice in England as a dentist. But Parliament passed an act in 1878 instituting a system of examination and registration. Under this, certain foreign diplomas are recognized, but, in the case of Americans, only those of Harvard and the Michigan schools. Drs. Huntley and Coe had diplomas of Pennsylvania and Boston schools. The British Dental Association, taking advantage of the wording of the act, summoned them to a police court yesterday for practicing without qualification. Mr. Waddy, an eminent Queen's counsel who appeared for the defendants, urged with much good sense that the act was never intended to exclude properly qualified men. The magistrate reserved decision. It is quite likely the act will have to be amended. Serious injustice is being done meantime.

Conversion of Mercuric Chloride into Calomel.

The conversion of mercuric chloride into the mercurous salt (calomel) in compound syrup of sarsaparilla was the subject of a paper read before the Indiana Pharmaceutical Association by Samuel Kennedy, of Shelbyville. The addition of 4 grains of corrosive sublimate, free from mercuric chloride, to two fluid ounces of the compound syrup of sarsaparilla, as well as to the same quantity of a watery infusion of each of the drugs entering into the composition of the syrup, showed, after standing ten days, considerable variously colored precipitates, and, upon testing, the presence of calomel was determined. With the addition of 12 grains of the mercuric chloride to the same quantity of similar specimens, the reduction into mercurous chloride was still more marked; but it was greatly retarded by the addition of an equal quantity of salt. Sodium chloride seems to facilitate the solution of the mercuric chloride, and the author thinks it advisable to add it in equal proportion to such mixtures.—*Western Druggist*, July, 1888.

Leprosy in Chicago.

August Johnson, a Dane, aged 21 years, was admitted to the County Hospital at Chicago on August 16, suffering from tubercular leprosy. Johnson came to this country when three years old, and enjoyed good health until eight months ago, when the loathsome disease appeared in the form of a small red blotch on his right loin. He is now covered with tubercles. The origin of the disease is a mystery to the Chicago physicians.

American Climatological Association.

The fifth annual meeting will be held in the Grand Army building, Pennsylvania Avenue between Fourteenth and Fifteenth Streets, N. W., Washington, D. C., September 18, 19, and 20, 1888, in connection with the Congress of American Physicians and Surgeons. The following is the official programme:

Tuesday, September 18, afternoon session, 2.30 o'clock: The President's Address, Dr. A. L. Loomis, New York. After this, the following papers will be read: A Study of the Climate of Colorado as Applied to the Arrest and Cure of Pulmonary Disease, by Dr. S. A. Fisk, Denver; Invalids Suited for Treatment at Colorado Springs, by Dr. S. E. Solly, Colorado Springs; Is Climate an Etiological Factor in Graves's Disease? by Dr. R. G. Curtin, Philadelphia; Health-Resorts *vs.* Institutions, for the Treatment of Pulmonary Consumption, by Dr. P. H. Kretzschmar, Brooklyn.

Evening session with Congress: Papers on Intestinal Obstruction in its Medical and Surgical Relations will be read by Dr. Reginald H. Fitz, Boston, and Dr. Nicholas Senn, Chicago, Ill.

Wednesday, September 19, morning session, 10 o'clock: The Influence of Semi-Tropical Latitudes on Types of Diseases, by Dr. John Guitéras, Charleston.

The discussion on The Relative Importance of Different Climatic Elements in the Treatment of Phthisis will be opened by Dr. E. T. Bruen, Philadelphia, and Dr. V. Y. Bowditch, Boston; Indications and Contra-Indications for Altitude in Treatment of Phthisis, by Dr. F. I. Knight, Boston; An Environment Experiment Repeated, by Dr. E. L. Trudeau, Saranac Lake; An Epidemic of Cerebro-Spinal Meningitis in Central New York, by Dr. W. T. Ford, Utica; The Physiology of Respiration in High Altitudes, by Dr. F. Donaldson, Jr., Baltimore.

Afternoon session, 2.30 o'clock: Report of the Committee on Mineral Springs, by Dr. C. C. Rice, New York, the Chairman; Therapeutic Value of Mineral Waters: In Gastro-Hepatic Diseases, by Dr. Wm. Pepper, Philadelphia; In Urinary and Arthritic Diseases, by Dr. A. H. Smith, New York; In Malarial Diseases, by Dr. W. C. Van Bibber, Baltimore. The Therapy of Ocean Climate, by Dr. A. L. Gihon, U. S. N. A banquet will be given at 6.30 P.M. Members may send their names to Dr. Bosworth, 26 West 46th Street, New York.

Evening session with Congress: Papers on Cerebral Localization in its Practical Relations will be read by Dr. Chas. K. Mills, Philadelphia, and Dr. Roswell Park, Buffalo.

Thursday, September 20, morning session, 10 o'clock: Conditions which Tend to Render the Atmosphere of a Locality Aseptic, by Dr. J. T. Whittaker, Cincinnati. The discussion on The Relation of the Nasal and Neurotic Factors in the Etiology of Asthma will be opened by Dr. Frank Bosworth, New York, and Dr. E. L. Shurly, Detroit; Climate and Bright's Disease, by Dr. J. C. Wilson, Philadelphia; Therapeutic Differences of Mountain and Sea Air, by Dr. W. H. Geddings, Aiken; Climatic Characteristics of Texas, by Dr. Morse K. Taylor, U. S. A.; Climatic Characteristics of Roan Mountain, East Tennessee, by Dr. C. Y. Kenworthy, Jacksonville; Weak Hearts as Affected by Climate and Temperature, Dr. J. J. Levick, Philadelphia; Temperature and Relative Humidity, and their Relation to Health and Disease, by Dr. J. M. Anders, Philadelphia.

Afternoon session, 2 P.M.: The first part of this session will be devoted to business.

Interpleural Pathological Products: their Cause, Significance, and Specific Relationship to Pulmonary Phthisis, by Dr. J. R. Leaming, New York; The Management of Phthisical Patients Undergoing Climatic Treatment, by Dr. I. H. Platt, Lakewood; Further Contribution to the Study of Consumption among the Indians, by Dr. W. Matthews, U. S. A.; Observations on the Use of Terebene, by Dr. D. M. Cammann, New York; Notes of a Summer in Switzerland, by Dr. D. B. St. John Roosa, New York; The Climate of Colorado, by Dr. W. A. Jayne, Georgetown, Col.

Evening session: Address of President of the Congress, Dr. J. S. Billings, U. S. A., after which there will be a general reception in the Army Medical Museum Building.

NEWS.

—Black measles of a most virulent type is said to have broken out among the negroes on the rice plantations on Santee River, S. C. Fifty deaths have already occurred.

—On August 20, M. Pasteur read before the Academy of Sciences a letter from Dr. Gamaleia, of Odessa, announcing the discovery of cholera vaccine. The announcement was favorably received.

—Up to August 27 there have been about 115 cases of a disease which local physicians call "typhoid malaria" in Bristol, Rhode Island, and about 12 deaths. The cause of the epidemic is said to be due to impure milk and water and a defective sewage-system.

—Surgeon General Hamilton has directed Dr. Stratton to inspect the trains between Washington and Alexandria, and to examine the tickets in order to discover all passengers coming from the fever-infected points intending to stop over in Washington. Such persons will be closely watched. It is not intended to quarantine the city, but to keep a lookout for refugees.

—The number of deaths in Philadelphia for the week ending August 25 was 454, which was an increase of 15 over the previous week, and of 36 over the corresponding period of 1887. Of this number, 143 were children under one year of age, and 210 were adults, and 244 minors. Of this number, there were 44 from cholera infantum and 41 from typhoid fever.

—The Marine Hospital Bureau is informed that there are now under treatment at Jacksonville, Florida, 62 cases of yellow fever. There have been 107 cases up to August 27. The deaths have numbered 17; discharged cured, 28; still under treatment, 62. Many of those under treatment are convalescing. A death from yellow fever is reported at Fernandina, and the bureau has authorized the mayor of Savannah to send an inspector to that place.

—In connection with our editorial on the Morris Plains Asylum, REPORTER, July 28, it may be of interest to our readers to learn that Dr. Edward C. Booth, who has been Medical Director of the New Jersey State Asylum for the Insane, at Morristown, has resigned. He states, in his letter to the Board, that he is constrained to this action by inability to effect needed reforms in the medical department of the asylum, owing to the opposition of the warden and certain members of the Board.

HUMOR.

BILL NYE, THE HUMORIST, sent the following brief dispatch in reply to an invitation to attend the recent banquet of the Indiana State Medical Society: "Sorry I cannot be there. May you and your associates continue to *take life* easily, as heretofore."

PAY YOUR SUBSCRIPTION.—An exchange relates this parable: "A revivalist requested all in the congregation who paid their debts to rise. The rising was general. After they had taken their seats, a call was made for those who did not pay their debts, and one solitary individual arose and explained that he was an editor and could not pay because all the rest of the congregation were owing him their subscription to his paper."

METROPOLITAN EDITOR: Think you need change and rest, eh? Well, I shouldn't wonder; city life is a hard one, taking it all the year round, and I believe it is several years since you had a vacation. Which do you most enjoy: seashore, mountains, or pastoral scenes? Hard-worked Reporter (with enthusiasm): Oh, the mountains, always. Editor: Well, the Mind and Matter Association will hold its sixteen-hour-a-day metaphysical sessions at the Bleak Top this year, and you can go there and report them. Don't miss anything, and keep each day's essays down to six or eight columns. The paper has a bill against the hotel-keeper at Bleak Top for advertising. I will charge it to your account and let you take it along. Just before leaving, hand him the bill in payment for your board; but be careful and do it politely, because he's a retired prize-fighter and the wickedest man east of San Francisco.—*Omaha World.*

OBITUARY.

JOHN MILLER, M.D.

Dr. John Miller, of Andover, N. J., died August 8. He was seventy-two years old, and was graduated from the College of Physicians and Surgeons, New York, in 1846.

JOHN F. MURPHY, M.D.

Dr. John F. Murphy died in New York City, August 12. He was a graduate of the Georgetown Medical College, of the class of 1873.

THOMAS J. GALLAGHER, M.D.

Dr. Thomas J. Gallagher, a prominent physician of Pittsburgh, who was graduated from the University of Pennsylvania in 1849, died August 21, aged sixty-six years.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

Prof. Alfred Stillé, Prof. Wm. Goodell, Prof. D. Hayes Agnew, Prof. H. C. Wood, Prof. R. A. F. Penrose, Prof. Wm. Pepper, University of Pennsylvania, Prof. J. M. DaCosta, Prof. Roberts Bartholow, Jefferson Medical College, Prof. Chas. K. Mills, Philadelphia Polyclinic.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled **Norwegian Oil,** rendering it by common consent the **Best Emulsion in the market.**

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

PRIVATE HOSPITAL FOR NERVOUS DISEASES

3240 Chestnut Street,

PHILADELPHIA.

THIS institution is designed to combine comfortable surroundings with the appliances and advantages of a special hospital. *Particular Provision is made* for the use of electricity, massage, rest and regulated exercise in neurological work, and for the use of strong electric currents in the treatment of abdominal and pelvic tumor cases.

Cases of Insanity Not Received.

G. BETTON MASSEY, M.D.,

NASAL POLYPI.

BY G. ARCHIE STOCKWELL, M.D., F.Z.S.,
PORT HURON, MICHIGAN.

Properly, the term "nasal polypi" is employed to describe myxomata or mucous tumors found within the nasal fossæ. By "nasal fossæ," are understood the two chambers, separated by a septum, limited in front by the so-called "anterior nares" or openings of the nose, and at the back by the "posterior nares" or openings into the upper pharynx and naso-pharynx at the posterior border of the septum.

Almost all tumors found within the naso-pharyngeal cavity proper are fibrous or fibro-mucous polypi, having a structure more or less dense and hard; and the great majority of growths found in the nasal cavities are mucous polypi. Papillomata, enchondromata, osteomata, and other tumors of the nose are exceedingly rare, and consequently do not require to be commented upon in this connection.

The term nasal polypi indicates: (1) The habitat of the tumor; (2) the fanciful resemblance of it to the group of radiates or zoophytes peculiar to the animal kingdom that bear the title of *polyps*.

These growths vary in size from a small pea to a marble or larger, and are generally attached by pedicles, though sometimes they are also found of sessile nature. In the main, too, they are more or less pear-shaped; or, as Dr. Markham expresses it, resemble in form, color, and consistency the "expressed pulp of the grape." Sometimes, however, very odd and irregular shapes are assumed, more especially when two or more coalesce at an early stage of their existence, ultimately developing as a single growth. The last kind, nevertheless, is of somewhat rare occurrence.

The bony walls of the nasal cavities and naso-pharynx are lined with a fibrous layer which has all the functions of periosteum, the superficial stratum alone being mucous. The former is thicker and more fibrous at the base of the skull, in the upper part of the naso-pharynx; consequently the origin of fibromata generally is there. In the vault of the nasal cavities, where the termini of the olfactory nerves are spread out, this membrane is thin; upon the septum, and also the floor of the nasal passages, the membrane is not of marked thickness or development; consequently, neither of the places is often the seat of polypi.

The mucous membrane covering the turbinated bones, especially the middle turbinated, and the meatus which they overhang, is decidedly thickened and vascular, and here acinous glands are abundant. Beneath the superficial layer of mucous membrane is found connective tissue. Upon the surface epithelium are *cilia*, which vibrate toward the posterior nares and serve as strainers for respired air. Here, again, where the mucous membrane is thick and vascular, is found the source of nearly all mucous polypi, and, like all such growths, they partake of the character of the material from which they spring.

Regarding the histology of these growths, Leiter remarks: "They are localized hypertrophies of mucous membrane which has undergone myxomatous degeneration"; a statement echoed by Hartmann. Billroth says they retain the elements of the mucous

membrane from which they spring, the glandular element sometimes predominating, sometimes the connective-tissue element. Gross employs nearly the same words as Leiter. Lefferts corroborates these statements in the following words: "They are enlargements of the acinous (grape-like) glands, with attendant hypertrophy of submucous tissues, and covering mucous membrane with serous infiltration, so that the membrane is pushed or drawn out by the gradual increase of the growth—in other words, localized hypertrophy."

Regarding the site of polypi, careful examination of the statistics and observations of various writers reveals the following: 1. Growths of this character positively never arise from the vault or floor of the nasal cavities. 2. They are of extremely rare occurrence in connection with the nasal septum. 3. Are seldom or rarely connected with the inferior turbinated bone. 4. Generally are from the superior meatus, middle turbinated bone, and middle meatus.

The first statement is based upon the fact that careful examination of voluminous (periodical as well as text-book) literature of the past half-century fails to reveal a single case. This is of especial interest in connection with the causes which produce them, of which more further on.

Of the second, authors are generally reserved in opinion; but the discovery of seven cases recorded is evidence of the possibility of such occurrence.

Of the three last, the middle meatus is the region most frequently infested. But, before citing further evidence in this connection, permit me to call attention to a few essential facts:

It must be remembered the middle meatus is situate beneath the overhang of the middle turbinated bone, and that in this meatus is found the gap or opening known as the *hiatus semilunaris:* that into this hiatus the maxillary sinus has its outlet, as have also, through the infundibulum, the frontal sinuses and inferior cells of the ethmoid. In other words, very nearly (or perhaps quite) nine-tenths the area of the air-spaces or cavities surrounding the nasal passages opens into this middle meatus.

Zuckerkandl, in thirty-nine autopsies, determined the nasal fossæ as the exact seat of forty-two polypoid growths or series of growths. Of these, 14 originated at the edge of the *hiatus semilunaris;* 8 at the outlets of the cavities opening into the *hiatus;* 10 in the middle meatus proper; and 4 from the middle turbinated bone. In short, 85.7 per cent. originated in the region of the middle meatus or middle turbinated bone.

Polypi, when found attached to the nasal septum, an exceedingly rare occurrence, as before remarked, are almost invariably adherent to the posterior portion thereof, and in the erectile-tissue area so ably described and demonstrated by Professor Bigelow, of Harvard, within the past decade.

The period of life during which nasal polypi appear is generally given as between the ages of sixteen and seventy. Regarding the latter, I may be permitted to express some doubt, since senility is not favorable to such growths, and, when discovered, they are probably of some years' standing. As regards the former, Dr. Ingalls, of Chicago, records a case in which the polypi originated in the thirteenth year; Morell Mackenzie, giving the statistics of two hundred cases, never encountered a polypus in individuals under sixteen years of age; Bosworth reports two cases in adolescents, however, one eleven years old, the other fifteen years old; and Mason reports one at twelve years.

Strangely enough, the first case that came under personal observation was that of a German lad in his fourteenth year; and the first presented to my brother, Dr. Charles Bliss Stockwell, was that of a boy only eleven years and three months old, and the attention of the parents was called to the growth by the fact it was about protruding from the anterior nares. Neither of us has since observed a case in a person of less than eighteen years of age.

As to sex, careful comparison of statistics reveals that males are much more prone to the disease than females, the proportion being sixty-seven per cent. in favor of the former.

Again, with regard to frequency of occurrence. Zuckerkandl—who, so far as I am aware, is the only person who has manifested sufficient interest in the pathology of nasal polypi to undertake autopsies with the especial view of adding to our stock of information regarding such growths—declares that he found polypi in an average of one of every eight post-mortems.

Almost invariably nasal polypi appear in clusters and in both fossæ: authors universally unite in the declaration that a single polypus is of such rare occurrence as to be almost phenomenal, and I know of no reason for combating or criticizing the statement.

In reviewing the character of polypi, and their effects as produced upon the human economy, it is discovered their relations are

of more especial interest to general practitioners than is perhaps often surmised, and for the following reasons: 1. All nasal polypi possess hygromic or hygroscopic characteristics, by which they absorb moisture in damp atmospheres, and give it off again in dry weather. Swollen by respiratory gases saturated with moisture, if possible they more tightly cork or occlude the chief chamber of the nasal apparatus, and the openings of cavities adjacent thereto. In this way an existing discomfort is increased. 2. The presence of polypi, by the irritation produced, induces greater or less secretion of mucus, according to circumstances. 3. By closing the nasal passages, they prevent mucus from passing back to the pharynx, as nature intended it should, giving a backward dip to the floor of the nasal fossæ, and a downward and backward inclination to the turbinated bones. 4. Air, in its passage to the lungs, instead of being warmed by the radiating vascular turbinated plates, is, owing to obstruction afforded by polypi, forced to seek ingress by the mouth. By this means, the lungs receive respiratory gases at a lower temperature than is proper, and such as, moreover, are improperly filtered, which is never the case where the nasal passages remain unobstructed Here we see the reason why, with certain diseases of the nasal passages and upper pharynx, pulmonary involvement so frequently appears as a sequel.

The connection between nasal polypi and asthma is oftentimes very intimate, as has been ably demonstrated by Voltolimi and Joal; indeed, the latter is not infrequently wholly dependent upon the former. And here permit me a suggestion in passing:

Note how frequently, at times, an asthmatic attack disappears when relief is obtained from a coryza; or how a case of bronchitis is relieved by removing some cause which has the effect of obstructing the nasal passages. Mark, too, how readily a paroxysm of "hay-asthma" yields when the puffiness and irritability of the erectile tissue of the posterior portion of the nose are remedied—quieted, for instance, by a spray of volatile oil of eucalyptus or solution of erythroxylo-caffeina, permitting the air once more to find its way by the natural passage to the lungs! When the mechanical obstruction is removed, the wheezing and inharmonious rasping of the bronchi quickly cease; and in many, perhaps a majority, of the cases, the asthmatic groanings and creakings are cries for nasal relief. The asthma itself may be produced as the sequel of mechanical obstruction, or merely an irritation derived from reflex cause.

Polypi may, and often do, so obstruct the lachrymal duct by pressure, as to cause flooding of the eyes, and this may be the first indication of their existence. Again, headache is induced, the severity of which depends upon like or similar causes, and is manifested by drooping lids and dull and suffused eyes: here there is a closing of the infundibulum or ostium frontale, preventing proper ventilation of the frontal sinuses. The frontal headache attendant upon so-called "cold in the head" is of this class, regardless of the presence of actual polypi, and may often be relieved by the use of Politzer's air-bag, employed in the same manner as in inflation of the middle ear through the posterior pharynx and Eustachian tube: the ventilation of the frontal sinus relieves congestion which has resulted upon temporary closure of the openings. Persistent cough, too, is frequently a condition or symptom, relieved by the removal of polypi which, alone or by their secretions, cause tickling of the posterior pharynx, and induce thickening of the palatine tissues. Sneezing is oftentimes another indication of the presence of such growths, bearing in mind, however, the application of the old saw: "All rabbits are hares, but all hares are by no means rabbits."

It is even possible for polypi to cause marked disfigurement of the nose and face, though, happily, this is rare. This is true of the German boy before noted as being my first patient of this class. He is now grown to man's estate, and would never permit any attempts looking to permanent removal of his troubles. However, his physiognomy was such that polypi were unable to work any material change for the worse. Recently, a second case came under observation, under the care of a brother practitioner, in which the bridge of the nose was greatly broadened, and to such a degree as to present the typical so-called "frog-face." In this case, the trouble began thirty-five years before, or when the patient was about the age of nineteen or twenty. Marked deformity, however, is of infrequent occurrence, except when the trouble is of long standing and is induced before the full growth and development of the individual were attained. Morell Mackenzie declares: "Facial disfigurement is so rare that it may be dismissed from consideration"; and some authors have been at pains to deny its occurrence altogether.

I must confess, moreover, to have been among the skeptics until convinced to the contrary by ocular evidence. Evidently, like all rules, those referring to polypi are capable of exceptions.

Epileptic convulsions I find cited as one of the evidences and results of polypoid growths, but such are necessarily of greater rarity than face-distortion, and are of reflex origin; hence they are deserving of merely passing mention. The primary cause of polypi is among the many things open to conjecture. Morell Mackenzie frankly admits his ignorance, and Bosworth is equally frank. Two writers suggest their production to be the sequel of long-continued swelling and infiltration of the mucous membrane from which they spring. Be this as it may, the causes undoubtedly are many and varied; they may be dependent upon either general or local mal-nutrition or reflexes. Further, careful examination of the surroundings and locality of the habitat of such growths, while it may not reveal absolute causes, certainly affords some clue to effects.

Note that the middle and superior turbinated bones are portions of the ethmoid. The ethmoid cells, moreover, are developed about the fourth or fifth year of childhood. In the formation of these cells, the spaces in the upper portions of the nasal cavities are probably encroached upon, and the process of narrowing the recesses by the bending and twisting of the cartilaginous and bony plates is evidently now inaugurated. That this encroachment increases with physical development and growth is not to be gainsaid; hence, that it is a factor in polypi-production would seem evident from the fact that growths do appear as early as the eleventh year. Two surfaces touching one another may induce irritation and secure an increased flow of mucus. The surfaces thus approximated readily retain portions of the excreted material, the flow of which is stimulated. Accumulated mucus always becomes more or less inspissated; and such a tenacious clinging mass, dragging upon the mucous lining where it is vascular and plentifully provided with connective tissue, evidently may, and does, at times, cause a yielding which results in the development of polypi. From the statistics already given, based upon examinations of cadavers, the actual attachments in thirty-six out of forty-two cases were at points over which the mucus from the cavities adjacent to the nasal fossæ must flow.

Among the causes necessary to the production of polypoid growths, then, we appear to have: (1) Narrowing and contraction of certain portions of the nasal cavities; (2) irritation of mucous membrane; (3) mucus more or less inspissated, and therefore tenacious; (4) a vascular surface well supplied with connective tissue, and capable of being dragged upon by tenaciously-adherent mucus acting as a mechanical force!

When there is no irritation in the nasal passages, no crowding of one part by another, and when all the cavities and the meatus are readily reached by the to-and-fro currents of air, excessive moisture and excessive mucous accumulation, and the apparently essential conditions to polypus-production, do not exist. In the young (prior to the tenth or eleventh year), excessive secretion and other abnormal conditions favorable to such growths may have place, but it is probable there is greater tonicity and firmness of mucous tissue, not easily overcome by accumulated and dragging secretion; and certainly the amount of connective tissue is less.

The symptoms of nasal polypi demand no especial mention, since they have already received general attention in speaking of effects. And definite diagnosis, of course, must be had as the sequel of ocular inspection of the nares. Examination through the anterior nares, made by means of the forehead mirror and speculum, or, better yet, a pair of curved dressing-forceps in lieu of the latter, will invariably disclose polypi, if such exist, and they always appear as white and glistening, or pearly-white, obstructions. If, as is sometimes desirable, the posterior nares are to be inspected, a rhinoscopic or the smaller laryngeal mirror is employed. The condensation of moisture upon the latter during use is readily obviated by warming slightly over a lamp. If, on touching the supposed growth with the blunt end of a probe, the point under impact yields, or the body is movable, there can be little doubt as to the correctness of prior conclusion.

Many methods of treatment have been suggested from the time of Hippocrates down to the present. Four hundred and eighty years before our era, the "Father of Medicine" employed sponges for this purpose, attached to cords passed through the nose to the posterior pharynx and returned through the mouth; by traction with a reverse movement, the growths were brought forward with the sponge. Galen employed astringents; Celsus the actual cautery; Paul of Ægina the knife and tenaculum; William

of Salicet (1546) was the first to introduce evulsion by forceps, a method that yet holds its own with general practitioners, as well as with many teachers. One hundred and fifty years subsequently, Valsalva suggested the removal of a lamilla of bone for the purpose of preventing the recurrence of polypi. Robertson (1805) invented and employed the snare. Finally we find no less than six methods still advocated, viz.: 1. The method of Hippocrates; 2. Removal by snare; 3. Evulsion by forceps; 4. Galvano-cautery; 5. Topical application of astringents; 6. Caustics and escharotics.

(1) To revive the first has recently been sought by McRuer, of Maine; but the method obviously has nothing to recommend it and meets with little if any favor. (2) Snaring of late years is generally performed by means of wire *écraseurs*, notably those of the Jarvis pattern. The introduction of the loop is not always easily or readily accomplished, is productive of more or less pain, and, after adjustment, the suffering produced by tightening and the process of removal is sufficient to prevent the patient from undergoing a second torture usually necessary to clear wholly the nasal passage of morbid growths. (3) Evulsion by forceps, for all it has held its place for many years, and is so extensively taught and recommended, even by some of the most eminent members of the profession, is a most barbarous procedure, and withal uncertain, unsatisfactory, and dangerous. Not only is the pain evolved thereby often most excruciating, but free hemorrhage obstructs the view after the first effort, and the operator is compelled to grope blindly for that which cannot be discerned. Not infrequently it results in tearing and lacerating healthy tissues. Such surgery is only comparable to that of the Indian *powah* who, with a pair of bullet-molds, tore away a soft palate and elongate uvula to relieve a hacking cough. The end does not justify the means, considering the other methods available. Again, most polypi spring from the region of the middle meatus, and ordinary forceps cannot reach the pedicle. Even though the turbinated bones be wrenched from their attachments or removed piecemeal, the growths invariably return. It is a question, to my mind, whether evulsion does not favor subsequent production of these bodies.

(4) The galvano-cautery is open to the same objection as the snare, and is even more tedious and painful, and especially liable to injure surrounding and sound tissues. Further, it is an appliance of the specialist rather than the general practitioner.

(5) Astringents, especially tannic acid, are recommended by an authority no less eminent than Thomas Bryant, who advises their application to the growths by insufflation. Twenty years since, I employed tannic acid in two cases with excellent results; subsequently it proved a complete failure so far as removal was concerned, though generally procured more or less temporary relief; it is palliative rather than curative.

(6) Caustics at the present day meet with favor, especially glacial acetic, carbolic, and nitric acids, and tincture of iodine. The former (glacial acetic acid) is especially satisfactory, save for the pain induced, and the difficulty of confining it to the growth alone. The others are open to like objections, and the additional one of unpleasant fetor arising from the slow death induced. Of late years chromic acid has proved most satisfactory in my hands, as it is totally devoid of the unpleasant features accruing to other caustics and escharotics, since its properties are limited to the growth to be removed. It is a solvent of animal tissue, but rapidly loses one-half its oxygen, whereby it becomes a harmless sesquioxide, so that care is required only at the instant of application. Even should it touch sound tissue, a bit of cotton, wound on a probe and dipped in a four per cent. solution of cocaine, obviates all unpleasant consequences. Again, chromic acid is antiseptic and disinfectant; is ten times stronger than carbolic acid; fifteen times stronger than nitric; twenty times stronger than mercury bichloride. The pain resultant from its application is merely nominal.

A saturated solution of chromic acid made fresh with water (*beware of touching with alcohol unless an explosion is desired!*), or the crystals merely moistened, may be applied by means of a fine glass rod or glass brush, or a bit of cotton wound about a slender gutta-percha probe. No especial skill is required. Reflected light obtained by the forehead-mirror should be employed, however, to illuminate the interior of the nose, and the view enlarged, if necessary, by the introduction of the tips of a pair of curved dressing-forceps. The growth absorbs the acid quickly, which insures its death, and the polypus comes away spontaneously in a few hours, or, at most, a few days, a second application being rarely required. Dr. Donaldson, who employs chromic acid, remarks that his invariable custom is to bathe and wash out the passages with lead-water

before applying the escharotic. This I have never done, and apparently no especial advantage is to be derived therefrom. As there are usually several polypi, as soon as one is removed, those behind should be attacked in the same way. Some few patients who had been treated by evulsion have spoken with great complacency of the use of chromic acid, as being pleasanter and nearly devoid of pain. Since it is so nearly painless, invariably effective, and does not upset or frighten either the timid or nervous, and is always within the reach of the general practitioner without especial aids or appliances, it cannot but commend itself.

THE CUTANEOUS EFFECTS OF QUININE.

BY J. M. FRENCH, M.D.,
MILFORD, MASS.

The cutaneous effects of quinine and its allies are not frequently met with, and probably for that reason but little is said of them in the books. Yet when they do occur, they are the source of extreme annoyance to the patient, and very likely of much perplexity to the practitioner, who, when he has administered a dose of any of the alkaloids of cinchona as an antiperiodic, for example, finds, on the following day, as was once my ill-fortune under similar circumstances, that, while the malarial manifestations have disappeared, they have been replaced by certain cutaneous symptoms more disagreeable than those of the original disease, and which he is unable to trace to their source. And when, after repeated administration of the remedy in the same case, he has established to his own satisfaction the relation of cause and effect between the drug and the symptom, he is fortunate if the confidence of the patient in him has not been impaired to such an extent as to prevent his ever having an opportunity to verify his diagnosis by a repetition of the experiment in subsequent attacks

The forms of cutaneous eruption which have been met with as the result of the administration of Peruvian bark or its alkaloids are numerous and varied. Nearly all of them, however, may be included under the heads of erythematous, urticarial, eczematous, or purpuric.

The *erythematous* form is probably the most common. Out of 60 cases reported by Morrow, 38 were of this variety. These were generally described as scarlatinal, but occasionally as rubeolar or erysipelatous.

The scarlatinaform eruption was first described by English authors. In Gassaway's case, it was accompanied by œdema of the face. In Heming's, it came on after the administration of one grain of quinine, was attended with intense itching, præcordial oppression, and a coated tongue, and was followed by slow desquamation. Skinner saw it appear in a woman after taking one grain, or even half a grain. It was accompanied by shivering and a violent chill, and was followed by desquamation lasting three months. Veeder reports a case in which the condition of the skin very closely resembled that of scarlatina. The patient had been taking small doses of quinine for several days, for a supposed malarial disorder, without consulting any physician. Becoming alarmed at the appearance of the rash, a medical man was called in. He found feverishness and general malaise, in addition to the scarlatinous erythema; but, fortunately suspecting the cause, he at once ordered the discontinuance of the quinine, when the rash promptly disappeared. It returned repeatedly, however, when, for the purpose of testing the correctness of his theory, quinine was given in small doses. Dr. Levassor describes a case in which there were high fever, rapid pulse, headache, and general malaise. The eruption soon appeared, and involved not only the integument, but also the mucous membrane of the fauces, but was not accompanied by pain or by any swelling of the tonsils. To complete the resemblance, it was followed by desquamation at the end of four days. Its true nature was not discovered until its recurrence some time later, after a second dose of quinine.

My own case, reported in the *Medical Record* of June 10, 1882, was similar to this in many respects, but its resemblance to a typical case of scarlatina was even more marked. The subject was an Irish domestic, having red hair, blue eyes, and a fair skin, who was suffering from tertian ague. Five grains of quinine or quinamine three times a day were sufficient to prevent the return of the chill, instead of which she suffered the next day from a diffuse erythematous eruption, which began upon the chest and arms, and spread over the entire body. On the forearm there were numerous miliary vesicles. There was also intense itching, with a high temperature—of which, however, much to my subsequent regret,

I kept no record. On the fourth day from the first administration of quinine, the symptoms continuing to increase in severity, a consulting physician of wide experience was called, and he unhesitatingly pronounced the case to be one of scarlet fever. At this time, it must be confessed, there seemed to be good ground for this diagnosis, as the rash was of a scarlet hue, the itching was intolerable, the febrile symptoms were moderately severe, and the tongue presented the typical strawberry appearance. The fauces were somewhat injected, but there was at no time any noticeable soreness or swelling of the throat. Recovery took place in due time, and was followed by copious desquamation. Soon after this, the patient was again attacked with chills and fever, and, on taking quinine, she suffered from a return of the scarlatinous erythema and accompanying febrile symptoms. Twice afterward —making four times in all—she underwent a similar experience, until all parties concerned were fully convinced of the cause.

The *urticarial* form of quinine-rash is represented in Morrow's list by twelve cases. These presented the typical wheals of urticaria, with œdema and puffiness of the face, which, in a representative case, were brought on by a single two-grain dose of quinine. There was also a sense of oppression in the chest, and a most intolerable burning and itching over the entire surface of the body. The symptoms subsided within twenty-four hours, but recurred upon a repetition of the dose. The patient was in this instance himself a physician, who had formerly practiced in a malarial district, and had been accustomed to taking large doses of quinine without any unusual effect.

Numerous cases have been reported of the *eczematous* form, as well as of a combination of the erythematous, papular, vesicular, and pustular varieties with the eczematous. Denk reports one in which the papules, developed upon an erythematous base, were transformed into vesicles, with the general features of an eczema. After the discontinuance of the drug, the vesicles dried up, and desquamation followed. In some cases, the vesicles burst and form thick crusts, simulating still further the features of an acute eczema.

The *purpuric* form is very rare, and consists of small ecchymotic spots like ordinary purpura, either localized or generally diffused. In Vépan's case, which was that of a woman suffering from neuralgia, these spots developed all over the body in two days after taking five grains of quinine in two doses, and disappeared nine days after the discontinuance of the remedy. This was repeated several times, the symptoms varying in intensity with the size of the dose. Morrow has observed the purpuric eruption in a boy of twelve years of age, following the administration of quinine for malaria; five three-grain pills were taken the first day, four the second, three the third, two the fourth, and one the fifth. Before this course was completed, purpuric spots had made their appearance on various parts of the body, but most abundantly on the lower extremities.

Still other forms of quinine-rash have been met with, though but rarely. Among those which have been described are the roseolar, bullous, and gangrenous.

Not only has the quinine exanthem resulted from the internal administration of the drug, but similar eruptions have been known to follow its external application, as in the case of workers in quinine-factories, and persons using ointments, pomades, and washes containing quinine. This suggests that the result in all cases may be due to the local action of the drug upon the skin, either directly when used externally, or by elimination through the glandular system when given internally. It will probably be found, also, that more cases occur in persons having sensitive skins than in tough-skinned individuals. Certain it is that the majority of cases reported have been in women and children, in whom the cuticle is more sensitive than in adult males. In my own case, the subject had red hair, blue eyes, and a light and sensitive skin. It would be interesting to know how this may have been in other cases, but, so far as I am aware, these facts have seldom been noted.

The appearance of the quinine exanthem is said to be more common in summer than in winter, and to affect eczematous persons most frequently. The liability—or idiosyncrasy — may be either hereditary or acquired. Future observations in these directions are needed before a satisfactory theory can be formed.

—Prof. Billroth, who led the opposition, a few years ago, to the admission of women to the Continental medical schools, has created something of a sensation in Vienna, it is reported, by having Dr. Grace Walcott and three other American women physicians repeatedly in attendance at his private clinic lately, to witness his own operations.

THE ETHICS OF OPIUM HABITUÉS.

BY J. B. MATTISON, M.D.,
BROOKLYN, N. Y.

In a paper by the writer, on "The Ethics of Opium Habitués," read before the Society of Medical Jurisprudence and State Medicine, New York City, June 14, 1888, and reported in the REPORTER July 7—reprint at command—attention was called to the prevalent opinion that all opium habitués are liars—an opinion that the writer declared, from his experience, to be unjust and untrue.

Distinctly asserting that the purport of his paper did *not* apply to "those who, viciously indulgent, and lacking alike in principle and purpose, take opium from mere sensual desire," he held that the statement "no morphia habitué can be depended on to tell the truth" was "so often at variance with the fact, that it must be the outcome of an experience with the baser class of cases, or added evidence of the 'cruelty of ignorance,' or an unwarranted libel on a worthy class of unfortunates," and that, among the better class of habitués, this asserted lack of veracity did not entirely obtain.

Regarding the origin of the opiate neurosis, the writer asserted that, among the class of habitués to which his paper referred, a "physical necessity"—painful conditions of body or mind—for which opium was given, usually by professional advice, and continued until it had created a disease of its own, was the great genetic factor, and not merely sensual indulgence or vicious desire. In an experience covering the history and treatment of hundreds of cases, but two exceptions to this statement had been noted.

Attention was called to the peculiar power of opium to ensnare and enslave—"a power of which the laity knows little or nothing, and the profession appreciates less than it should." "The writer had been studying opium and opium habitués for more than sixteen years, with an annual experience of late, as regards number of cases, probably unequaled in this country, and yet he stood more and more in awe of this peculiar power with every case that came under his care." Some striking instances were presented.

Granting this "physical necessity," and opiate conditions beyond control, it was asked "on what principle of equity or right can one be held accountable, and so, culpable, for his use of the drug, when, unaware of its ensnaring power, and confiding in the counsel of his medical adviser, he avails himself of the relief it affords? What right has one to set himself up in judgment to note the beam in his brother's eye, when the only reason it is not in his own—when the only reason he is not an opium habitué—is because a kind Creator has so conditioned him that this physical necessity, and consequent opiate need, does not, with him, obtain?"

While admitting that the habitual use of opium often prompts to falsehood, the writer advanced the opinion that, in many cases, "the leading factor in this moral obliquity is the principle of self-protection—the habitué's desire to shield himself from that censure which the prevalent opinion—uncharitable and untrue—that he is simply the victim of his own vicious indulgence, involves."

In closing, these conclusions were submitted:

"Reason and right alike demand a more rational and correct idea as to the origin of the toxic neurosis we have noted.

"This demand complied with—regarding such patients, with certain exceptions, as creatures of conditions beyond control, and so no more culpable than the subjects of other functional disorder—will be most helpful against the protective temptation to untruth.

"The medico-legal status of such cases will then be more in keeping with advanced forensic medicine.

"The medical care of these cases will tend to a more humane method, with larger promise of good results, both near and remote.

"It will, too, be likely to lessen the increase of habitués and the number now existing; for a more correct idea as to the genesis of this disorder will prompt medical men to greater care in avoiding the cause, while many a patient, who now shrinks from disclosing his misfortune, feeling that he is not denied the charity that his case deserves, and that he can command resources both helpful and humane, will be impelled to avail himself of the aid that scientific treatment can surely extend."

In the discussion following this paper, one gentleman said "it was the first time in his experience that, in the discussion of a medical topic, a better and a poorer class of patients had been spoken of," and "the author had failed to define the meaning of 'better class.'" Neither criticism is correct; for no reference whatever was made to a "poorer class," the expression being "baser class"; and the writer *did* define the

"better class" as those who—without regard to riches, learning, or social standing—became opium habitués *unwittingly*, from implicit confidence in, and trustful following of, their physicians' counsel, until the continued use of the drug had created a condition from which they could not, unaided, escape; and the "baser class" as those who take opium from vicious tendency or mere wanton desire. Is there not a difference? And should there not be a distinction? Is the *onus probandi* in exculpation alike for both? As well might it be said that the physician who, in pursuit of his calling, or the innocent wife or child who, in the interchange of sexual and social amenities, becomes poisoned with syphilis, is as culpable as one who contracts this disease in the usual way!

It was further asserted by this critic that "in the great majority of cases, the opium habit was contracted through a selfish purpose or vicious tendency," and that "nine out of ten persons who applied for admission to homes for opium habitués were those who had become acquainted with the drug as doctors and nurses, not through taking it for long suffering." The truth of these statements we *emphatically deny*. Dr. Spitzka's assertions are disproved by men of much larger experience than his, and by *statistical facts*, without which a mere *ipse dixit* goes for naught.

Dr. Joseph Parrish, for many years medical director of a sanitarium for alcohol and opium habitués, said in 1872: "Men take it not for pleasure, but for a physical necessity."

Dr. E. H. Van Deusen, Ex-superintendent of the Michigan Inebriate Asylum, wrote: "For the primary induction of the habit, the stated physician is so commonly responsible that the *onus probandi* in exculpation rests upon him by all fair presumption."

Dr. Albert Day, Washingtonian Home, Boston, whose experience covers more than a quarter-century, writes: "Most of the opium cases I have treated, and I do not know but all of them, began with physicians' prescriptions."

Dr. T. D. Crothers, Walnut Lodge, Hartford, Conn, reports: "All the opium cases I have studied show distinct physical causes as a starting-point of the addiction."

Obersteiner says: "The first commencement of the use of morphia is almost always some painful ailment."

Levenstein declares: "The originators and propagators of this disease are the medical men who, in cases more or less painful and protracted, have advised the patients to use the injection of morphia."

Erlenmeyer, in his recent work—now being translated by the writer—asserts: "The causes of the morphia disease are all those painful conditions of body and mind against which the drug is used."

The writer's opinion—"Pain is the parent of opium addiction"—quite accords with those given.

Of twelve cases cited by Sonder, eleven had a painful origin. The exception was a case of alcoholism.

Of twenty-four cases noted by Levenstein in his work, twenty-one began with pain. Of the others, one, a surgeon, to relieve insomnia; a doctor, and a doctor's wife, to combat mental anxiety.

Of fifty cases mentioned by Erlenmeyer, forty-eight were from physical disease. The exceptions were in a case arising from mental excitement, and one from depression.

Of one hundred cases most recently under the writer's care, ninety-eight had their origin in pain. The exceptions were a naval surgeon, from sea-sickness, and a young doctor, whose curiosity to know the effect of opium outranked his good sense, and wrecked him for life.

Dr. Spitzka's statement as to the proportion of doctors and nurses among opium habitués who present themselves for treatment is incorrect. While admitting that physicians make a majority of the professional class,[1] it is not "nine out of ten," nor because they "become acquainted with the drug" through their calling. Erlenmeyer says: "The assertion that physicians become habitués by virtue of their frequent handling of morphia is true in only a small percentage of cases."

For statistical proof of this position, I submit the following facts lately secured from the superintendents of several inebriate asylums:

Dr. Lett, Homewood Retreat, Guelph, Ont., reports: "Physicians, forty-five per cent.; nurses, *nil*."

Dr. Crothers, Hartford: "Physicians, fifty per cent.; no nurses."

Dr. Earle, Washingtonian Home, Chicago: "Physicians, thirty-six per cent.; no nurses."

Dr. Day, Boston: "No physicians; no nurses. Patients were merchants, farmers, clerks, etc."

[1] See "Opium Addiction among Medical Men," *Medical Record*, April 9, 1885.

Dr. Blanchard, Inebriates' Home, Fort Hamilton, L. I.: "Physicians, thirty-four per cent.; nurses, eight per cent."

Mr. Bunting, Home for Intemperate Men, New York City: "In 1887 we cared for fifteen opium cases, of which five were physicians and two nurses."

Of 50 cases cited in Erlenmeyer's work, 16 were doctors, 1 medical student, no nurses.

Of 110 cases noted by Levenstein, thirty-five were doctors, two nurses.

Of 125 most recent cases under the writer's care, sixty-two were doctors, one a nurse.

Of the 300 cases we have cited, 124 were doctors and nurses, instead of 270—less than half—if Dr. Spitzka's statement, "nine out of ten," were correct!

Dr. N. S. Brill referred to the baneful effect of opium on the *morale*, and said "this influence, he believed, was transmitted from generation to generation." This opinion calls for no comment other than to mention the rule—exceptions not frequent—that the habitual use of opium makes the male impotent and the female sterile, and under *such* conditions it is difficult to conceive of *any* influence "transmitted from generation to generation."

USE OF ETHYL BROMIDE IN LABOR.

BY GEORGE B. SIMPSON, M.D.,
WESTON, W. VA.

In communicating this short article, my object is to get the experience of some of my fellow-physicians as to their use of bromide of ethyl in parturition. I began using it some time ago, and intend to continue it whenever my patient will consent, provided she has no physical contra-indication. I usually aim to lessen the acuteness of the pain of the first stage by giving bromide of potash and chloral hydrate, twenty grains of the former with ten grains of the latter every one or two hours. At the beginning of the second stage, I resort to the bromide of ethyl, by administering from two to four drachms in the same manner as ether and chloroform are used. I do not find it necessary to go beyond the point at which pain is obtunded at first, and, as labor advances, I keep pace by increasing the amount, and prolonging the inhaling to semi-unconsciousness. In this way my cases have progressed to the end of labor without the least untoward symptom. Generally the child is expelled without the knowledge of the mother, and then, upon inquiry, she will say that she had some recollection of the passage of the head. The pains, if any difference occurs, are more regular than when no anæsthetic is used; they are, moreover, strong, and do their work apparently without any assistance derived from the use of the voluntary muscles. The effect on the circular fibres of the os uteri is very noticeable after the first inhalation, the general relaxation is pronounced, and it seems an easy task for the patient then to endure the agony of child-birth. Another thing in favor of bromide of ethyl, as compared with either chloroform or ether, is that it does not possess the strong, pungent, and lasting odor which belongs to the last named. On the other hand, the smell is not disagreeable. Nausea is not usual after its use, whilst it generally follows the administration of ether or chloroform. I will here mention, for the benefit of some who may read this article, and who have never used any anæsthetic in labor, something which books fail to teach, which is, that it is not necessary to have the patient inhaling the anæsthetic during the whole time occupied in labor; remove the napkin after each pain, and replace it about a minute before the next pain returns. Direct the patient to take deep, full inspirations. This will give ample time to develop sufficient anæsthesia to blunt the severity of the pain, which is all that is necessary during the second stage. At the close of labor, the effect can be increased to full anæsthesia, if this is deemed prudent.

I have not seen anything in the journals of late respecting the use of bromide of ethyl. As I have been written to for information regarding its use in labor, I thought, in order to enlist an interest in it, I would give my limited experience, and would like to hear from others who have had more. I feel that it is not only safe, but is a God-send to poor suffering woman; and, as our duty demands us to be diligent in our efforts to relieve the sufferings of humanity, we should not fail to utilize every remedy which will aid in the relieving of pain, and thereby also gain the encomiums of our patients.

—Florence Nightingale is now a patient at a London hospital, which she herself founded. It is said that she is suffering from an affection of the spine, which originated as long ago as the Crimean war, when she ministered so faithfully to the wants of the sick and wounded soldiers.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, June 12, 1888.

C. B. Nancrede, M.D , in the chair.

Dr. John S. Miller read the following paper:

A Contribution to the Study of Bone Repair.

The recent observations of Macewen[1] have done much to stimulate the study of bone repair, and have thrown not a little light upon the function of the medullary cells in osteogenesis.

The resort to mechanical irritation of the medullary tissues as a means of accelerating bone repair is an old procedure. Nancrede[2] claims a priority in this for America. As far back as 1793, Eve[3] relates that the lay surgeons of the frontier were wont to make multiple perforation of the external table of the skull where necrosis had followed the Indian mutilation of scalping. And, twenty years ago, Agnew[2] resorted to the same procedure in a case of injury to the head. A fatal termination of the case, however, by encephalic complication, rendered the experiment incomplete. Reports of success by this procedure have been recently multiplied to an extent which will excuse us from repeating them in detail.

That, furthermore, medullary proliferation is not only an element in osteogenesis, but is of itself sufficient to that end without periosteal co-operation, is evidenced by the case of Macewen,[4] in which a considerable restoration of the humerus was secured "by bone-transplantation," after a suppurative inflammation had destroyed both the shaft and its periosteum. The date of this observation is 1878.

The patient was a boy, two years of age. A suppurative periostitis of the right humerus of nine weeks' duration had resulted in total necrosis of the entire diaphysis, and this latter had been removed, leaving a tube of granulation-material lining the periosteum. This tube had been kept patent by suitable dressing, until the whole space had become filled with granulation-tissue, and had finally become a mass of cicatricial tissue. No bone had grown from this periosteum, except in a small part next the proximal epiphyses, where at the outset the periosteum had been found covered with plaques of adherent osseous tissue. In the remainder, there had been no osseous deposit, the result being a flail-like arm, which the patient found so useless that the parents desired its removal.

Macewen determined, however, upon another procedure. An incision was made into the upper third of the arm, exposing the head of the bone, to which was found attached a spike-like process of cartilage. This was removed, leaving as remains of the diaphysis a portion of bone one and three-fourths inches in length. From this point, a sulcus about two inches in length was made in a downward direction between the muscles. The former presence of bone was nowhere indicated, and there was no vestige of periosteum, and the sole guide as to the correct position into which the transplant was placed was an anatomical one. Two wedges of bone were then removed from the tibia of a patient aged six years, with anterior curves. The face of the osseous wedges consisted of the anterior portion of the tibia, along with its periosteum, the wedges gradually tapering toward the posterior portion of the tibiæ.

After removal, they were cut into minute fragments with the chisel, quite irrespective of the periosteum. The bulk of the fragments had no periosteum adhering to them, they having been taken from the interior of the bone.

They were then deposited into the muscular sulcus of the boy's arm, and the tissues drawn over them and carefully adjusted. The wound healed without pus production. Two months after, a portion of bone an inch in length and three-quarters of an inch in thickness was found firmly attached to the upper fragment of the humerus.

Two other wedges of bone, larger in size, were similarly dealt with, and inserted two months subsequently to the first graft, and a third couple were placed in position five months after the first. These filled up the gap in the arm to the extent of four and one-quarter inches. The arm then measured six inches in length.

Soon the utility of the arm was greatly restored. Seven years afterward, he was seen and examined. The shaft of the humerus was found to have increased in length by one and three-quarters inches, being now seven and three-quarters;

[4] Loc. cit., p. 301.

and it had increased in circumference to a marked extent, and assumed a somewhat irregular shape. The length of the sound arm had, however, considerably outstripped the length of the transplanted humerus. He could use the arm for many purposes, taking his food, adjusting his clothes, and many games.

Whether the introduction of proliferating medullary cells into ordinary connective-tissue granulations may convert the whole into osseous tissue, or that a few osteoblasts will, so to speak, leaven the whole mass, is a question involving grave doubt, but the affirmative would seem to receive some support from the case which Nancrede[1] relates in 1883. An extensive laceration had caused denudation and necrosis of the ulna in two-thirds of its extent. The process of repair had been delayed. He drilled numerous holes through the sequestrum into the medullary canal, and, to quote his own words, "in a few days granulations sprang up from the ulna and fused with the granulations of the soft parts, and, in course of time, the fragment was separated."

That the procedure in this case had the effect of stimulating osteogenesis from within, we can readily believe; but, concerning the fusion with granulation-tissue without, a more accurate observation than is recorded by Nancrede is desired, although by analogy we might conceive it possible, inasmuch as repair within the bone is by ossification of an embryonic tissue derived from the connective tissue around the blood-vessels of the medullary spaces. A similar case is reported by Macewen,[2] in which granulations appeared upon a surface of bone completely denuded of its periosteum, and gradually spread until they became united with the granulation-tissue at the periphery of the wound. Macewen, however, infers from this observation that: "The periosteum covering a bone may be completely destroyed or permanently removed, yet the denuded bone may not only retain its vitality, but may throw out cells which will cover it and form a new periosteum."

These cases would seem to confirm Macewen's dictum that the periosteum has no part whatever in the regeneration of bone. But the first case I shall present to your notice this evening demands a different hypothesis for its explanation.

[1] Transactions of the Philadelphia Academy of Surgery, 1888.

[2] Loc. cit., p. 293.

The patient, D. M., aged fourteen years, suffered from an osteomyelitis of the right tibia, resulting in total necrosis of its diaphysis. A complete involucrum had formed around the sequestrum, and afforded an unsteady support to the body-weight. It was covered with the thickened periosteum. A number of fragments had been removed from time to time, and the parents had refused to entertain for him the proposal of amputation. The case, however, when it came into my hands, had become, from septic infection, so desperate that I was compelled to do something radical at once.

Exposing the shaft, or rather the involucrum, through its whole length, I made, with trephine and saw, a fenestrum large enough to permit the removal of the remaining sequestra, and cleared out the whole canal. Both epiphyses were found carious upon their exposed surfaces, and were scraped to the limit of safety. In a few days, a superficial necrosis took place upon the inner surface of the tube.

Demarcation was, however, promptly effected by the free use of aluminum acetate[1] —that sheet-anchor in all sloughing wounds—and a fine layer of fine granulations became the field for any osteogenesis which we might hope to witness. During the long process of repair, with the carious epiphysis as a never-failing source of bacterial supply, it was no trifling task to keep this extensive opening dry and sterilized. Furthermore, neither the patient, the household, nor the neighborhood could endure frequent dressings without great nervous prostration.

The requirements of the case were successfully met by a mixture of iodoform and starch, in proportions which varied with the changing conditions. The cavity of the wound was filled with this dry powder, and to the whole was applied a closed dressing of gutta-percha tissue. The purpose of the starch was to absorb the excess of moisture incident to a closed dressing, as well as to dilute the iodoform. As soon as the powder became saturated, it was removed by a stream of sterilized water, and the wound was filled and closed as before. The periods of dressing were gradually increased from three to ten days. I mention these details, because, without them or similar ones, we can wait in vain for the desired repair. In process of time, the hollow of the involucrum became completely filled with granulation-tissue, which continued to extend until it

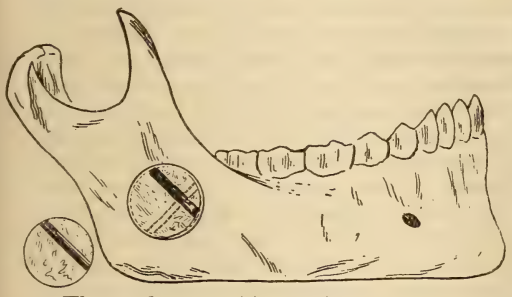
[1] ℞ Pot. et alum. sulph., 1 part; plumb. subacet., 5 parts; aquæ bull., 100 parts. M. Filtra.

fused with the granulations from the soft parts, and finally the whole became covered with a new epithelium, which had gradually spread from the edges of the wound. The tissues became now denser, and offered more and more support to the body-weight until, as you see, he has acquired a very useful limb, and can walk without discomfort.

We must, therefore, infer that a metamorphosis into bone has taken place, and, as the original diaphysis was gone with its medullary structure, we can find no osteogenic agent in the result other than the periosteum.

We must draw a similar conclusion from the recent case reported by Ceci:

The patient, a young man, developed an acute osteomyelitis of the left scapula five days after circumcision for inflamed phimosis. One month later, Ceci[1] extirpated the bone, making the usual L-flap. The periosteum was left intact as far as possible, and the arm was preserved. The patient recovered rapidly, and there was a subsequent regeneration of the bone.



The only possible explanation of this result is by the hypothesis of periosteal agency or co-operation.

The second case which I present is in confirmation of Macewen's proposition that "A portion of bone which has its continuity severed on all sides, and has had all its periosteum removed, is capable of living and growing."

This is in contradiction to our inference in the case of the tibia, and can be reconciled only by the assumption that the discovered laws of osteogenesis are of a lower order, subject to some general law of which we are as yet ignorant. But to the case.

Mrs. L., aged forty-seven years, had suffered with a neuralgia of the maxillaris inferior, for the relief of which all medical means had been exhausted in vain, and which, therefore, left to my option only the *dernier ressort* of neurectomy. The mode of operating was the usual one. The ramus was trephined near the angle of the jaw, the canal was exposed, and about two inches of the nerve-trunk were drawn out and exsected. The button was, however, returned after having been sterilized in a 1 to 1000 solution of corrosive sublimate, but it was not returned to its old position. With a view of imposing a barrier to the reproduction of the nerve, it was so rotated around its vertical axis that the groove upon its lower surface stood at right angles to the axis of the canal. Not only did the wound close by first intention, but the button grew solidly in its position. Now, the curious thing in the case is, that before trephining I had carefully removed the periosteum, so that the latter can claim no part in the subsequent bone repair. After seven months, there has been no return of the disease.

[1] Centralbl. f. Chirurgie, Dec. 17, 1887.

Dr. John B. Roberts, in opening the discussion, said: It is a curious fact that the medical mind has not appreciated the possibility of bone production, despite the frequent instances that must always have come under notice. I was taught, in cases of comminuted fracture, to take out the spicules of bone that were entirely separated from the larger fragments, lest they should necrose and give rise to trouble. Now, it is the practice of the best surgeons to leave the spicules, and we find that often they do not die, and that they assist in the process of union and solidification. This experience is in the same line as the facts given by Dr. Miller in connection with his interesting cases. If these spicules of bone can reunite, why not the button removed by trephining? Why is it not good practice to insert, when necessary, a portion of dog-bone or chicken-bone? as, indeed, has been done. We must not forget, however, the importance of asepsis, and that it is antiseptic surgery that has made these procedures possible.

In a case such as Dr. Miller reports to-night, where he rotated the button of bone, turning the groove, in which the inferior dental nerve had run, at right angles to its former direction, I should be inclined to go still further, and turn it upside-down. The bottom of the pit in which it is to be placed and the periosteal surface of the button being scraped, the ungrooved freshened surface, formerly external, would then be placed inward, and a bony plug would be interposed between the divided ends of the nerve, probably preventing the reunion and return of pain which so often occur.

The case of tibial resection has been very interesting to me, as I have recently operated upon a similar one; the patient being, how-

ever, a woman of about fifty years, so that I cannot hope for as complete a closure of the cavity in the bone as in this growing child exhibited by Dr. Miller. In that case, I removed the whole front of the tibia, going as near the articular cartilages above and below as I dared. The process of repair is like that we see in a tree. We know that, if a foreign body is inserted into a wound made in the trunk of a young tree, the process of cell-growth will go on about it, and finally it will be completely covered in, and its presence be unsuspected until, perhaps, the saw strikes it, as the tree is being converted into lumber.

Dr. Keen, in his recent case of trephining for brain-tumor, returned the button of the skull removed, and the patient was able in a few days to walk around with a perfectly-healed and reunited cranium. Then we know what the dentists do in the way of transplantation of teeth, or return of teeth to their original sockets after removal of diseased portions. More remarkable still is the implanting of old dried teeth into new sockets bored in jaws from which even the alveolar process has disappeared, and their becoming fixed there.

Dr. George E. Stubbs: In reflecting upon these cases and similar ones, it occurs to me that perhaps, in the numerous resections we have done in army and in civil practice, we have made mistakes. Surgery has advanced immensely since the war-time, and antiseptic surgery has opened new possibilities. Often, in my army practice, we removed all the bone when there had been a comminution. I should now, with our new light, try to save more of the broken bone, and so shorten the period of recovery.

In regard to operative treatment of neuralgia, I believe that we are entering upon a stage of work that will be much enlarged in the near future. I had a case recently in which neuralgia of the inferior dental nerve had existed for nearly seven years. I removed one and three-fourths inches of bone with the dental engine, took out as much of the nerve as I had access to, and dressed and treated the wound antiseptically. The wound healed by first intention, and as yet there has been no return of pain; so that I consider I have obtained a very good result.

The Chairman, Dr. Nancrede, said: The first question to be answered in a discussion of this kind is: What constitutes the periosteum? If we mean a fibrous membrane, the inner layer of which consists principally of yellow elastic tissue, then we must agree with Macewen's extreme views, and admit that it has nothing to do with bone repair. But, if we study the normal process of bone development, I, at least, must arrive at a different conclusion. The long bones are laid down in cartilage, a temporary structure. How do they ossify? By means of this very periosteum, which Macewen treats with such contempt, and which Ollier exalted too highly. There is a third layer of the periosteum in direct contact with the bone, and this layer is composed entirely of those elements which, wherever we see them, we recognize as the agents of ossification—the osteoblasts. The temporary cartilage is invaded by connective tissue, ingrowths from the periosteum, covered with osteoblasts, and is eaten up by them; and we find it permeated, and finally replaced by a network of fibrous tissue covered with osteoblasts. A certain number always remain beneath the periosteum. A certain number, very small, remain in the Haversian canals, a still larger number in the medulla.

It is clear to me why compact tissue dies; it has so few osteogenetic cells. The medullary tissue lives because it is comparatively rich in osteogenetic elements. Why does bone die when the periosteum is stripped off? Because the resulting inflammation is so severe that the inflammatory tissue strangulates the osteoblasts in the Haversian canals. With antiseptic means, we now control the inflammation, and the osteoblasts are not killed, and the bone is saved.

We are very hard, nowadays, on the periosteum. The fibrous layer has nothing to do with bone repair, but its osteoblastic layer is in direct communication, through the lining of the Haversian canals, with the medulla; it is practically one structure; and thus, if we look at this matter from the standpoint of a correct histology, we find that both views are correct, provided only that we have a distinct understanding what is meant by the word periosteum in each case.

As to Dr. Miller's cases, I cannot quite agree with him as to what formed the bone in the case of total excision of the diaphysis of the tibia. While the shaft was dying, new bone was formed by the deep layer of periosteum; but, after that, the medullary spaces of the involucrum completed the bone. I would also take exception to Dr. Roberts's proposition to scrape the button of bone and turn it inside-out, in the case of trephining the jaw for neuralgia. By this process he would remove all the osteoblastic cells, and the compact tissue would have a

very good chance of dying. One reason for failures in operations about the lower jaw is that it contains so little true medullary tissue, while, on the contrary, we can replace trephine-buttons in the skull and have union, because the skull contains a large amount of such tissue.

I think Dr. Stubbs need not blame himself for his practice in resecting in military surgery. The necessary condition to bone repair is that absence of suppuration afforded by antiseptic methods, and, under the conditions present in the operations he speaks of, he did right. And, to-day, he does right in trying to save the bone. In each case, he takes the proper course in relation to the circumstances, and that is all anyone can do.

The case of Dr. Agnew, referred to in the paper, occurred some twenty odd years ago. I saw the operation. The wound was completely covered by granulations. The fact that a denuded external table did not always necrose was known to Potts and to all the older as well as modern surgeons, and, if Ollier had not led us astray by grafting, by insisting upon the periosteum being the sole osteogenetic agent, ignoring the fact that, in removing it, a layer of cells identical with those of the medulla is torn off, I think we would have arrived at a correct practice sooner. But surgeons went wrong by authority of Ollier, as they are now going wrong in the other direction by authority of Macewen.

In regard to the implantation of dead teeth, which Dr. Roberts refers to, the principle is probably the same as in the bony pegs we used to employ for ununited fractures. They are hollowed out by the granulation-tissue, which develops into a fibrous or even osseous tissue, and so holds the tooth in place by these newly-formed digitations. About twelve years ago, I exhibited to this Society a case in which I resected four and a half inches of the humerus, and about two and a half inches were reproduced from the sawed end. This was without antisepsis. In the case referred to by Dr. Miller, where I drilled the ulna, I am sure that the bone granulations fused with those of the soft parts, for these reasons: the shell of bone, when detached, was not more than one-fourth the thickness drilled through, while the new bone was nearly as thick as the ulna of the other side, as the cicatrix was not materially depressed. A recent experience in a case of knee-joint excision induces me to recommend that, instead of wiring fragments of bone, we nail them together, after having previously drilled, or not, according to circumstances, allowing the heads of the nails to project through the skin. We thus save trouble, and avoid damage in the removal.

Dr. Roberts: Dr. Nancrede misunderstood me in regard to scraping away the cancellated tissue in reversing the plug in the case of trephining the lower jaw. I would scrape only what he calls the fibrous periosteum from the button, and from the bottom of the pit in the jaw I would take away the cancellated structure sufficiently to remove all trace of the nerve-canal. The two raw surfaces would be placed together, and, by sinking of the button, would be a solid bony plug interposed between the nerve ends.

Dr. Miller: I do not see any advantage in reversing the plug over rotating it. The groove being at right angles to the course of the nerve, the part in contact with the nerve is still solid bone, and the groove does not matter at all. In relation to the tibia case, the reason I emphasize the fact that the repair took place from the periosteum is because there was entire death of the old bone with the involucrum, while the periosteum did not die.

THE NATIONAL ASSOCIATION OF RAILWAY SURGEONS.

FIRST ANNUAL MEETING, AT CHICAGO, JUNE 28, 1888.

The preliminary meeting of the Association was held at Chicago, Illinois, June 28, and was called to order by the Chairman of the Committee, Dr. C. W. Stemen, of Fort Wayne, Ind., who said the salient feature of the meeting was for permanent organization. The objects of the Association were to bring the surgeons of the different railroads together annually to develop this special and rapidly growing branch of surgery, to report cases, to relate experiences, to exchange views, and to discuss the best means and methods of treatment in railway injuries.

The meeting was very largely attended, nearly all the distinguished railway surgeons of the United States being present. Sixty-three railroads were represented. The Association starts out with a membership of 600, and promises to be one of the most active surgical organizations in the country.

Dr. W. B. Outten, of St. Louis, read a paper on

A Few Points in Railway Surgery.

He said that out of 103 railway injuries attended by him—caused by the passage of locomotives and cars over the parts involving the superior and inferior extremities, excluding injuries of hands or feet—more than one-third died from shock, and one-tenth died from shock without operative interference.

Dr. J. B. Murdock, of Pittsburg, in opening the discussion, said he had been deeply interested in Dr. Outten's paper, and, in discussing the treatment of railway injuries, the question of paramount importance is whether we should adopt primary amputation, or, as a rule, resort to secondary amputation. If he understood Dr. Outten aright, he recommended secondary amputation in limbs crushed by railway injury. The time at which an amputation should be performed is divided by some authors into the primary, intermediate, and secondary. Others make still further divisions. For instance, Dr. Hamilton does what he calls the *immediate operation*, then the primary, intermediate, and secondary. The primary amputation is made within twenty-four hours of the accident, the intermediate during the inflammatory period, and the secondary after suppuration has set in. He believed all authors agreed that that which was called the intermediate—that is, between the primary and secondary—is an unsafe and dangerous time to perform amputation, for it had been said by military surgeons that the mortality in primary is much less than in secondary amputation. That was the conclusion military surgeons arrived at. It is important for every railway surgeon to know whether he should adopt what has been confirmed by military surgery. It has been his rule, and he believes it to be the correct one, that, if the patient has sufficiently reacted from the shock, to perform amputation, and the sooner it is done the better, and the greater are the chances for recovery of the patient.

The modern rules of doing operations under strictly antiseptic precautions, it is true, have replaced old ones; many of the old rules were certainly useless, as far as statistics show. A great many of our patients die after amputation, from septic poisoning. He would ask those gentlemen who have had an extensive experience, if we are not able to obtain better results by primary amputation now than we ever did before? Do you know that, when we meet with a mangled badly-crushed limb in which vessels or arteries have been severed, we are more apt to have blood-poisoning if we wait, than if we do the amputation at once, before any change has taken place in the vessel or vessels? There is an increased proportion of benefit resulting from the primary over the secondary operation. Indeed, he would go farther and put himself on record in favor of the immediate operation, as a rule. He wanted it understood that he would not do this always. There was one point with regard to the manner in which a car-wheel crushes a limb which should not be overlooked. Frequently surgeons would say—and usually they were surgeons that have not had much experience—that they have saved limbs over which the wheels of a car had gone. Any surgeon who reflects for a moment upon the fact that the weight of an empty gondola car is about 17,000 pounds, and observes the mechanism of the flanges, which act, so to speak, like a powerful pair of scissors—if he will recollect, furthermore, that a pair of wheels weigh 500 pounds, a locomotive 50,000 pounds, and the lightest box-car 17,000 pounds—he will come to the conclusion that not many limbs are saved after a car-wheel goes over them. When a car goes over an object, about one-third of its weight rests upon the object as it goes over it. He had not much confidence in surgeons who claimed to save limbs over which car-wheels had gone.

Dr. W. P. King, of Sedalia, Missouri, had been doing surgical work for railroads about twelve years; he had charge of a large railroad hospital, and had treated, from time to time, a great many wounded men. It was an unfortunate circumstance for those who were injured on railroads to have to undergo amputation. While it is true in regard to other accidents and injuries to which men are subjected, that limbs are saved when seriously injured, it was also true, as stated by Dr. Murdock, that, when a car-wheel passes over an arm or leg, as a rule, that member must come off. He had seen one or two cases, and one particularly in which two car-wheels had passed over the arm of a man, leaving their imprints behind as they passed over. The limb was saved. The man carried a bundle under his arm at the time of the accident, which consisted of old clothes, and which, Dr. King held, saved the arm. He would not arrogate to himself the idea that he saved

the man's limb, or the limb of any man over which the wheels of a car had gone, for by so doing he would place himself in a position he would not care to occupy.

With regard to the wonderful influence that had been wrought upon railroad work by modern antiseptic surgery, he could maintain the position that it is not always necessary to cut a man's leg or arm off in order to prevent septic infection. He claimed to be a pioneer in the use of antiseptics in surgery in the West. He did not care how much a man's limb had been injured, contused, or lacerated, he could prevent blood-poisoning. In the first place, a certain time is required for the entrance of the ptomaines or septic material into the circulation; and, if the surgeon would apply an antiseptic apparatus, washing every part of the contusion and lacerated tissue carefully and thoroughly, he could prevent the entrance of septic germs.

Dr. J. H. Bennett, of Wauseon, O., would like to go back to the foundation of antiseptics. He had practiced his profession for 25 years, had done considerable railroad surgery, but had never applied carbolic acid or bichloride of mercury to a wound—in short, he had never used a drainage-tube. He held that, by using either bichloride of mercury or carbolic acid, he would be adding to that wound a material that would set up an inflammation.

Dr. J. B. Stemen, of Fort Wayne, Ind., said the points set forth in Dr. Outten's paper showed that the author has had a large experience in railway surgery, that he knows what he has written about, and understands the subject thoroughly. It was one of great practical importance to the railway surgeon. While he admired to some extent the remarks of the last speaker (Dr. Bennett), he could not let them pass without entering his protest against what had been said in opposition to modern antiseptic surgery. Being in a position, as railway surgeon upon the Pennsylvania road, where accidents occurred now and then, and sometimes but little or no attention had been paid to antiseptics in the dressing of wounds and sending the cases on to him, he had experienced serious difficulty. With the rapid advances that have been, and are being made in surgery, and from the testimony we have in this country and across the water, the day is past when men can consistently oppose antiseptic surgery. Sir Joseph Lister, in his teachings, has been the greatest benefactor of the present age in advocating it. He could demonstrate to anyone—and it was almost useless to discuss that question, for it had been demonstrated so often—the benefits resulting from an adherence to antiseptics in the practice of surgery. He regretted very much, indeed, that there are still men who oppose it. He knew that Lawson Tait, Bantock, and others did not directly advocate it, yet, in order that a person may visit their operating-rooms, he is almost bound to subscribe to an oath that he has not been in a dissecting-room or in the presence of any infectious disease before he is admitted. All the necessary antiseptic precautions were taken by them, with the exception that they do not use the bichloride.

Dr. J. H. Murphy, of St. Paul, said he had been a railway surgeon for 25 years, and the cases that most annoyed him and his assistants were injuries of the spine. He had at present one case under his care, of fracture of the spine, with paralysis of the lower limbs. Most patients with spinal trouble died. He would like to ask any member of the Association whether there was any manner or means by which such spinal injuries could be relieved. He had resorted to every known form of treatment, but had failed. If anyone had met with success in the treatment of such cases, he would like to know it, the plans adopted, etc

Dr. Outten closed the discussion by saying he did not wish Dr. Murdock to understand him as favoring secondary amputation It depended upon the nature and extent of the injury. In some cases, he would resort to primary amputation, in others he would not, but would endeavor to meet the indications.

Dr. Murphy moved that, when the Association re-assemble, it discuss injuries of the spine. It was in a large number of such cases that the railway surgeon was called upon to testify in court, and lawyers were better posted on this subject than anything else. *In short, they all read Erichsen.*

The Association convened again at 8 P.M., First Vice-President, Dr. J. H. Murphy, in the chair.

Discussion on Spinal Injuries.

Dr. Stemen, of Fort Wayne, opened the discussion by saying that, in 1874, a man working in a gravel-pit in Illinois sustained a fracture of the eleventh dorsal vertebra with compression of the cord and complete paralysis of the lower extremities. The patient was brought to his town in a pitiable condition. A short time after the injury,

he made the operation of trephining—cut down and removed an arch of the vertebra—with good results. Sensation was restored, and the bed-sores healed kindly within two weeks after the operation. The man is still living, and has served in Ohio three terms as Recorder of that County; but there is still some paralysis of the lower extremities.

In the same year, at Macon County, Missouri, he made the operation on a man upon whom a limb had fallen. He removed two arches of the vertebræ, without benefiting the patient. He had since done the operation three times: once for railway injury—the man was caught by a train and doubled up, and fracture produced. He did not get to operate on this case, however, for over a week, on account of having to wait to obtain consent of the family. He finally operated, with no benefit. What he desired to say more particularly was this: He believed the surgeon, notwithstanding what Ashhurst has regarded as unjustifiable, whenever he has fracture of the vertebræ with compression of the cord, and after obtaining the consent of the patient and his friends, should cut down and elevate the depressed bone, and, if there has been an injury of the cord, he believed the operation would be a successful one; and, although he had only met with success in one case, he regarded the operation as justifiable, and would advocate it.

Dr. David Prince, of Jacksonville, Illinois, reported the case of a man who was thrown out of a wagon by a runaway team; the end of the wagon fell across his back, paralyzing his lower extremities and bladder. The tenth dorsal vertebra projected considerably beyond the eleventh. The patient never recovered the use of the lower extremities, and, about a year after the accident, died. He thought the patient died principally from irritation connected with his helpless condition. In the light of what had been said by Dr. Stemen, he would not hesitate to cut down and remove an arch or two arches of bone and see what the results would be.

Dr. J. Harvey Reed, of Mansfield, Ohio, said it seemed to him that, as railway surgeons, we have to consider spinal injuries under two general heads: *First*, pseudo-spinal injuries; and, *second*, true spinal injuries. The worst class he had to treat, and which gave him the greatest amount of annoyance, was the *pseudo* class, which lawyers usually "trumped up." For instance, a fellow is hurt; he, perhaps, does not report to the surgeon at all, and, in the course of six months, sues the company. The surgeon is called upon to defend the company. The question comes up for the surgeon to decide whether that man really has spinal injury, or whether he has not. It is an important question—one that embraces finance and morality. The railway surgeon is morally bound to give that man the benefit of the injury he has sustained; at the same time, he is bound to support the company if the patient plays the part of an impostor. He had found, in his experience, that this class of cases was the hardest for him to decide positively as to diagnosis, and to do what he considered his conscientious duty to the road to which he belonged.

As to the cases of *true* spinal injury, there was no question about the diagnosis. If we have a fracture of the spine, with all the true results, it was not difficult to decide.

He would agree with Dr. Stemen that, where there is fracture, with compression of the cord, the proper thing to do was to cut down and relieve the pressure, just as we would relieve the pressure upon the brain from a depressed fracture of the skull. These fractures may be slight; the pressure may be slight; yet grave results sometimes follow them, just as they do slight pressure and injuries of the brain, which result fatally in six, seven, or ten years afterward. He was satisfied that surgeons had been too conservative in the matter of operating upon the spine. Dr. Ridenour, to his knowledge, had trephined the spine with favorable results; and he could not see any tangible reason, nor, in fact, any more danger attached to trephining the spine than in trephining the skull for lesions of the brain. If we can do it with impunity in the skull, why can we not do it with impunity on the spinal cord? He was firmly convinced that many difficulties could be relieved by trephining. It is true, these difficulties will sometimes be relieved spontaneously, just as gun-shot wounds of the abdomen, intussusceptions, etc., get well spontaneously. This was not the rule, however.

Dr. Reed then related a case of fracture of the atlas. The man recovered. The accident occurred five or six years ago; the man came very near dying last week. The injury that the fractured vertebra is producing on the spinal cord, in his judgment, will, sooner or later, produce death.

Dr. Murdock, of Pittsburg, thought it was the desire of the Association to have taken up the subject of Erichsen's Spine, so as to include all injuries from so-called spinal

shock up to that of fracture of the vertebræ and compression of the cord.

Fortunately, his experience was not very extensive, for he had only met with two cases of fracture of the spine, which, he regretted to say, terminated fatally. He thought, if any surgeon could instruct the Association how to treat fractures of the spine with a reasonable degree of success, whether by suspension, jury-mast, plaster-of-Paris, wiring, trephining, or otherwise, he would confer a great benefit upon the members.

In this connection, he saw the report of a case (he thinks in a Kansas journal) of a new-born child in which the spinal cord is said to have protruded, or separation taken place, a few days before birth, in which the doctor cut down, returned the cord, and wired all vertebræ separated together, and the child is still living.

What should be said of those cases in which we have supposed spinal injury without lesion? He would hold, and believed it to be true, that there is no such thing as a serious injury of the spinal cord without a lesion. He did not believe there could be such a thing as a paralysis, or any serious disturbance of the nervous system, such as we often heard complained of, without some kind of change in the structure of the cord itself.

Dr. W. A. Ward, of Conneaut, Ohio, fully agreed with Dr. Reed in regard to diagnosis. Although he had not had much experience with injuries of the spine, yet the remarks made vividly called to mind a circumstance in which he was placed. A lady in a wagon, attempting to cross a track, was struck by a gravel-train that was backing up. She claimed to be seriously injured, and commenced suit for recovery of damages. The case ran along, and was finally set for trial. Dr. Ward had no knowledge of the case whatever, but had received a communication from the counsel of the railroad, requesting him to examine the case and make a report of it. When he got there, they claimed that the lady was seriously injured; that she remained comatose for twenty-four hours or more. He took his time, examined the case thoroughly, went home, and wrote out his report to the effect that, although he believed the woman was injured at the time, it was only temporary, and that she was suffering from hysteria. He would not be surprised, as soon as the case was settled and out of the way, to see her make a rapid recovery. He called attention to the fact that she was injured at the outset, and remained comatose for a considerable time, which afforded an excellent foundation upon which the lawyers could build a case; but he considered the superstructure faulty and defective. The lady sued for $25,000, but the claim was adjusted for less than $2,000. A year or so afterward, he inquired about the lady, and learned that she was dead. He could obtain no facts in the case, and, while the question occurred to him whether he had erred in diagnosis, he was fully convinced that her death had no direct connection with the injury. Had the woman died before the case went to trial, he had no doubt the lawyers would have attempted to make the jury believe that death was directly and unmistakably attributable to the injury.

Dr. V. P. Gibney, of New York, being called upon to address the Association, said that, while he was deeply interested in the subject of spinal concussion, or Erichsen's spine, his practice had been limited in that direction. He would like to have some one tell him how to differentiate between the *pseudo* and *true* cases of spinal trouble. This was not an easy matter to do. He thought that, if we looked to neurology, we would be able to discover, at all events, whether there is any lesion or not. There were a few things in neurology with which the general practitioner could acquaint himself.

Dr. W. A. McCandles, of St. Louis, said that, something over six months ago, a brakeman was setting a brake, and the rod broke, throwing him back upon the car. He was brought to the hospital with lower extremities paralyzed. After being there some weeks, making no exhibition of any feeling or sensibility in the lower extremities, he became suddenly blind in one of his eyes and described the sensation as if a sharp body had pierced his temple. About the same time he lost his voice, so that for months whispering conversations were held with him. He was very much interested in the case, because the patient had every appearance of being a good, honest, sincere man. Dr. McCandles consulted a neurologist, ophthalmologist, and laryngologist, which constituted the consulting board of the department to which he belonged. It was some time before he consulted these gentlemen, however, believing that the conditions were genuine. The man lay in bed five months without apparently moving his limbs. First, the laryngologist was called, who, after examining his throat, said there was no reason why the man could not

speak and articulate distinctly, as the cords opposite came in contact with each other. Next, the ophthalmologist was called, who subjected the patient to the prism test, and said there was nothing to prevent him from seeing. Different tests were made to determine whether he could, by any possibility, be compelled to move his limbs. Pins were thrust into him without avail. His legs were œdematous, cold, death-like. The three specialists (Dr. Alt was the ophthalmologist in this case) saw nothing wrong with the man. Shortly afterward, he met one of his comrades and joined him in a drink, and, if the reports were authentic, the man proved to be a malingerer.

Dr. T. M. McIlvaine, of Peoria, Illinois, said that, some five years ago, he was sent 40 or 50 miles to see a woman who had, 14 months previously, received a railway accident in Iowa. She was thrown from her seat to the floor, striking on her shoulders. She immediately got up; made no complaint. Her clothing was torn somewhat, for which she received $20 on account, and signed a release as part of the damages from the company. She went home, resumed her usual vocation, and for five months made no complaint whatever; but shortly after this she complained of a tender spot in the spine, which seemed to increase. Various reflex symptoms came on—vomiting, urinary trouble, etc.—until the woman was totally disabled. Suit was brought against the railroad company for $5,000. Dr. McIlvaine was unable to find any lesion. He visited the surgeon who examined her at the time of the accident; there was no redness of the parts, and no pain. The case was traced, a detective put to watch the woman two or three months, she at that time living 40 miles from the railroad, in a small country town. The case proceeded to trial; she won it It was appealed, and she won it again. Dr. M. had kept track of the woman for five years, and she was absolutely perfectly helpless. Whether there was a palpable lesion or not, he was unable to say, but he thought there were a number of such cases that could not be controverted, and the railway surgeon may as well face the music. The best way to do is to follow them up to find out whether they are malingerers or not.

The following papers were read:

Report of Two Cases of Successful Triple Amputation for Railway Injuries, by Dr. J. B. Luckie, Birmingham, Ala.; Synchronous Amputation, by Dr. N. C. Lynd, New York; Report of a Case of Simultaneous Triple Amputation with Recovery, by Dr. A. J. Banker, Columbus, Ind.; First Care and Treatment of Railway Injuries, by H. H. Middlecamp, Mo.; Relations of Railway Surgeons and Members of the Bar, by Lagrange Severance, Ind.; External Wounds Communicating with Fractures of Bones, by Dr. J. R. Williams, Michigan; Report of a Case, by Dr. William Caldwell, Ohio; Treatment of Compound Fractures, by Dr. W. L. Buckner, Youngstown, O.; Brakemen's Injured Fingers, by Dr. J. A. Jackson, Milwaukee, Wis.; Fracture of the Spine with Reports of two Cases, by Dr. W. C. Henry, Indiana; Violent Injuries of the Pelvic Bones and Pelvic Viscera, by Dr. W. A. McCandles, St. Louis, Mo.

The following were then elected officers for 1889:

President, Dr. J. W. Jackson, Kansas City, Mo.; First Vice-President, Dr J. H. Murphy, St. Paul, Minn.; Second Vice-President, Dr. J. B. Murdock, Pittsburg, Pa.; Third Vice-President, Dr. A. W. Ridenour, Massillon, O.; Fourth Vice-President, Dr. B. L. Hovey, Rochester, N. Y.; Permanent Secretary, Dr. C. B. Stemen, Fort Wayne, Ind.; Assistant Secretary, Dr. J. H. Tressel, Alliance, O.; Corresponding Secretary, Dr. E. R. Lewis, Kansas City, Mo.; Treasurer, Dr. J. Harvey Reed, Mansfield, O.

St. Louis was chosen as the place of next meeting.

PERISCOPE.

Treatment of Broncho-Pneumonia in Children with Application of Ice.

Dr. Angel Money, Assistant Physician to University College Hospital, London, in a communication to the *Lancet*, June 2, 1888, says that he has treated many cases of severe broncho-pneumonia in infants and children with applications of ice-bags. The cause of the pneumonia does not, in his experience, influence the employment of the ice-bag. It may be used with much success even in cases of broncho-pneumonia secondary to tracheotomy, but still more favorably in cases occurring in influenza and measles. The smaller the child, the more marked, he says, are its effects. In very small infants, under one year of age, the ice-bag may be placed on the head, the hair having been previously thinned and shortened if necessary. The treatment, to be successful, must be carried out with a will and system-

atically. As a general rule, the temperature in the rectum affords the best guide to the application of cold, and those acquainted with broncho-pneumonia well know the highly-marked remittent or almost intermittent character of these affections. Ice-bags have the objection that they often give rise to a little wetting of the child; but this has not, in his experience, proved injurious to the patient. Leiter's tubes have been tried, and have some advantages, being especially valuable when an intelligent nurse is in attendance. In severe cases, in which a rapid effect is required, two ice-bags have been placed on the head and one over the chief seat of consolidation in the lungs. With a little management, he says, it is not difficult to keep these in place; certainly not when the neuro-muscular prostration is marked, as it almost always is in severe cases. The chief merits of this treatment, he says, consist in the maintenance of the strength, not only of the heart, but also of the respiratory centres and of the nervous and muscular systems. Although otitis media occasionally occurred, yet this has not been more frequent than in cases treated without cold. Albuminuria, he says, is not rendered worse by the cold, nor have any cases of hæmaturia been observed, although Dr. Money has been at some trouble specially to collect and test the urine. The duration of the disease he declares to be, on the whole, shortened. Convalescence is almost invariably rendered more rapid, doubtless because of the conservation of the child's energy.

Not only, he says, does the cold directly quiet the heart and steady the circulation, but the calming of the nervous system also acts indirectly in the same direction. The respiratory centres are similarly beneficially affected. The heat-regulating apparatus manifests more clearly the same beneficent action, and the temperature-chart shows a similar harmonious effect. It is curious to observe the almost immediate cooling of the whole surface of the body soon after the application of ice to any part, this cooling effect being perhaps best marked when the ice is applied to the head; the hands, previously red and hot, become cool and slightly blue. The change is decidedly favorable, notwithstanding the supervention of the signs of feeble circulation in the exposed parts of the skin. Vomiting and diarrhœa, alone or in combination, may require treatment in the cases under consideration; the cold method, he says, does not increase diarrhœa, but certainly tends to stave off vomiting. Stimulants are to be used when indicated, but they are less apt to be necessary under this treatment. There is, he says, a saving of expense all around: the cost of the illness is lessened and there is less expenditure of reserve strength.

Administration of Salol to Children.

Demme reports in the *Wiener med. Blätter*, No. 51, 1887, a number of interesting investigations made as to the action of salol on children. He employed this drug in four cases of articular rheumatism, two cases of acute endocarditis and pericarditis with but slight rheumatic complication, two cases of vesical catarrh, and as an external dressing in two cases of serious burns. Two of the patients with acute rheumatic polyarthritis were boys of eight and thirteen years of age. Both of these, as long as there was fever, swelling, and painfulness in the joints, received doses of fifteen grains of salol at intervals of two or three hours until forty-five or sixty grains had been given. In one of these cases, salol was given for five and in the other for seven days. With the reduction of the fever and of the joint-affection, the amounts of salol were reduced to thirty grains in a day, and, as convalescence was established, but fifteen grains were given. Although in these cases the effects of salol were not astonishingly prompt, yet, on the other hand, there was no relapse of the rheumatic process; so that the duration of the disease, in all, was only from fourteen to sixteen days. In the third patient suffering from articular rheumatism, a girl seven years old, the temperature was reduced from 103.4° to 98.8° F. within forty-eight hours after the administration of seventy-five grains of salol in divided doses, and was accompanied by the reduction of the painful swelling of the foot, right knee, and left elbow-joint. Here also no relapse occurred. The fourth case of rheumatic polyarthritis was that of a girl, nine years of age, in whom the result was less satisfactory. In the first place, considerable difficulty was met with in the administration of the drug. The administration of fifteen grains, whether in emulsion or capsules, produced vomiting within ten to fifteen minutes. After the introduction of thirty grains of salol in egg emulsion as an enema, there occurred within eight or ten hours an eruption of urticaria over the entire body, while no improvement was observed in either the fever or the joint-affection. The use of the remedy was therefore suspended, and

sodium salicylate, in doses of forty-five grains daily, substituted. This substitute was retained, and reduced fever and swelling and pain in the joints, but it likewise led to the production of an eruption similar to that caused by salol. For eight days after the employment of the sodium salicylate, the child was perfectly convalescent, but there was then a relapse of the disease, with the localization of the rheumatism in the right shoulder-joint and metatarsal joints of the left foot. Antipyrine was then given; and this was well borne, and cure resulted in four days, after seventy-five grains in all had been given. In the cases of endocarditis and pericarditis, the action of salol was satisfactory only when frequency of the heart's pulsation had been reduced by appropriate doses of digitalis. In the two cases of vesical catarrh, the salol was well borne. One of these was of special interest, as it was a case of acute cystitis from the toxic action of cantharides. At first, salol was given in doses of twenty-four grains, then of thirty-one grains, and then of thirty-nine grains, daily. On the second day, the alkalinity of the urine disappeared, and diuresis was more abundant and painless. The amount of pus and mucus in the urine decreased, and the boy was regarded as cured. Toward the end of the administration of the salol, a greenish-brown coloration of the urine occurred similar to that produced by carbolic acid.

Notwithstanding this result of Demme, we cannot believe that salol is destined to a high career in practical internal medicines, unless, indeed, it be as a remedy in diseases of the bladder. As our readers no doubt know, it yields, when broken up by the pancreatic juice, about sixty-four per cent. of salicylic acid and thirty-six per cent. of phenol. It cannot affect the system differently from the two substances which it contains, and neither clinical experience nor any scientific reasoning indicates that it has peculiar virtues; and the claim that it is incapable of producing untoward symptoms, and that it agrees better with the stomach than any other salicylic preparation, is doubtfully sustained. It is, however, less disagreeable to take than many other preparations of salicylic acid. But, in a considerable experience, we have been convinced that it is less prompt and less certain in its influence, especially in rheumatic cases. Bethol, although it contains ten per cent. less of salicylic acid than does salol, is probably not less efficient than salol, and is less poisonous, because it has in it the inert naphtholol instead of carbolic acid.—*Therapeutic Gazette*, July, 1888.

Accident from a Laminaria Tent.

Dr. Thomas C. Smith, of Washington, D. C., reports a case in the *Am. Journal of Obstetrics*, July, 1888, which illustrates an accident which may occur from the use of laminaria tents. A young married woman, who had never been pregnant, consulted him for dysmenorrhœa, from which she had suffered since menstruation began. On examination, he found a conical cervix, but there was neither displacement nor disease. On trying to pass a sound, the cervical canal was found to be of such diminished calibre that the instrument could not be made to reach the uterine cavity. A fine probe was finally made to enter the uterus. After some days of preparation, the patient was anæsthetized, and a straight sharp-pointed bistoury, cautiously used, was made to cut its way through the obstruction, enlarging the canal of the cervix sufficiently to permit the introduction of a sound with facility. A small laminaria tent was inserted and allowed to remain until the next day. It was Dr. Smith's intention to introduce a hard-rubber stem pessary to prevent the contraction of the parts; but, owing to severe pelvic pain due to a slight cellulitis, this plan had to be abandoned. For six or eight months, the woman suffered little from pain during her periods; but, after that time, the dysmenorrhœa was as bad as ever. In June of the last year (1887), he made an examination, and found the cervical stenosis greater than it was originally. A solution of cocaine was applied locally, and he was able to divide the stricture sufficiently to admit a sound. Next day, a small laminaria tent was inserted for the purpose of dilating the parts, so that a stem pessary might be used. On trying to remove the tent, he was surprised to find that it would not come away readily, and it was only by using considerable force that the tent was secured. The patient suffered much pain at the time, but this was not to be wondered at when the tent was examined. This was found to have expanded above and below the stricture, but at the point of constriction its expansive power had not been sufficient to stretch the parts, and, as a matter of course, difficulty was experienced in removing the tent, which looked as if it had been tied tightly in the middle with a string. For several days the patient suffered pain, but has menstruated with less pain since that time.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - - 6.00
Physician's Daily Pocket Record, - - 1.25
Reporter and Pocket Record, - - - - 6.00
Reporter, Compendium, and Pocket Record, 7.00

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CONGRESS FOR THE STUDY OF TUBERCULOSIS.

A very important gathering of medical men, devoted exclusively to the study of tuberculosis, took place in Paris from the 25th to the 31st of July. The chief questions submitted for discussion were: The danger of using meat or milk from tuberculous animals; the aptitude of human races, animal species, and organic tissues (*milieux*) to contract tuberculosis; the route of introduction and propagation of the tubercular virus, and prophylactic measures; and the early diagnosis of tuberculosis in man and the lower animals.

It would be hard to give, in a short space, a satisfactory summary of the work done at this Congress, and those of our readers who have opportunity may well turn to the full reports in the French journals, and especially in the *Gazette Hebdomadaire* and *Bulletin Médical*, and study them carefully. But, in order to give our readers an idea of what was brought forward, we may state that the questions proposed proved much too extensive to be fully discussed, and that the time of the Congress was largely occupied with discussion of the conditions which predispose to tuberculosis, and the manner of its communication. The general opinion seems to have been that heredity has a powerful influence in predisposing to tuberculosis, and that the disease itself may be hereditary. Not much seems to have been said in regard to the belief that the children of tuberculous parents inherit, usually, only a peculiar vulnerability, and not a disease, and that they simply give way to that one of the constantly pressing morbific influences which meets with tissues least fitted to resist them.

A great deal was said about the *rôle* played by milk and meat in provoking an outbreak of tuberculosis, and it seems to have been the general opinion that meat and milk from tuberculous animals are frequent sources of infection. In this connection, attention may be called to the discussion as to the possibility of infection through uninjured mucous membrane. A number of observers and experimenters testified that there could be no doubt that infection may, and does, take place in this way, although there was some strong negative testimony in regard to the liability of chickens to contract tuberculosis when fed upon tuberculous matter.

Some interesting communications were made in regard to the infection of human beings by means of wounds into which tuberculous matter was presumably introduced. The testimony given seems to warrant the opinion that infection in this way rarely gives rise to any more serious trouble than what is called "anatomical tubercle"; and it is reassuring to note that M. Barthélémy reported that he had invariably succeeded in curing this lesion

by the application of the actual cautery, in small points placed very close together.

From this brief sketch, it may be inferred —and the inference will be correct—that the Congress on Tuberculosis, while an important gathering, made only a beginning of the work which it may be hoped that subsequent meetings will carry further. In fact, it only dipped here and there into the subject, and decided nothing in regard to the questions before it. The nature of the disease received hardly any attention at all, and its treatment was almost entirely neglected.

One thing more must be said, in regard to the scientific value of the proceedings. No just estimate of them can be formed—unless it be by rarely discriminating minds—without some personal knowledge of those who spoke. All who have experience in such meetings know that what may read like a conclusive argument may come from one who has more ability as a disputant than as an observer; and that zeal in supporting an opinion often leads to a species of mental strabismus or intellectual scotoma, which must be taken into consideration in estimating the value of what some persons see or think.

Giving this fact its due weight, we incline to believe that the recent Congress on Tuberculosis may be regarded as having furnished nothing more than a series of interesting observations, which deserve the careful study of those who have already made tuberculosis the subject of special investigation; but that the chief value of its work was—as might have been expected at a first meeting—in indicating the lines upon which subsequent investigations may be most efficiently carried out. Judged by this standard, the meeting was a success; but we trust that not many will fall into the error of a newspaper of Chicago, which evidently thought that the Congress had settled the whole question of the mode of communication of tuberculosis, and had pointed out measures calculated to lessen very materially its ravages. There is a great deal to be learned about tuberculosis yet, and many meetings like that held lately in Paris may be held before we shall understand just how it comes, or how we may prevent its coming.

TREATMENT OF PHTHISIS WITH INTRA-PULMONARY INJECTIONS OF CREASOTE.

It is now about fourteen years since Dr. William Pepper, of Philadelphia, had the courage to attempt to bring about healing in cavities in the lungs, caused by phthisis, by the injection of iodine into the substance of the lung. After a faithful trial of this method, he finally abandoned it, as the results—while promising at first, and very satisfactory in a certain number of cases—did not prove good enough to warrant its general adoption. Other clinicians have, at different times since then, made attempts of a similar sort; but, so far, all have failed to establish the employment of intra-pulmonary injections as a method in the treatment of phthisis.

Lately, however, Dr. Leon Rosenbusch, in Lemberg, has made a number of experiments, in the General Hospital in that place, in the treatment of phthisis with intra-pulmonary injections of creasote, which have encouraged him to recommend this method for general adoption. In the *Wiener med. Presse*, June 10, 17, and 24, he describes his plan in detail, and gives the results of its employment in ten cases. He obtained the best results from injections of a three per cent. mixture of vegetable creasote with oil of sweet almonds This generally produced, after the first injection, a diminution in the coughing, and a considerable decrease in the fever of his patients, lasting from eight to twenty-four hours. At the same time, the general condition of the patients improved, and the physical signs of consolidation were lessened.

Rosenbusch thinks the period best suited for this sort of treatment is that of beginning disintegration of the apex; but he thinks

it of advantage even in the most advanced cases.

The method employed by Rosenbusch is to inject slowly, with a long needle, about thirty minims of the mixture of sweet-almond oil and vegetable creasote into the substance of the lung. The point to be chosen is where the part affected can be most easily reached. As the greater number of patients with phthisis are attacked at the apex of the lung, he generally injected through the second intercostal space in front or through the supra-spinous region at the back. In his experience, the injections gave little or no pain, and had no unfavorable effect. When he injected into a cavity or into a bronchial tube, the patient soon tasted creasote in his sputa. He recommends, naturally, that these injections be made with antiseptic precautions.

The strong commendation of this method by Rosenbusch has led others to test it, and Dr. T. Stachiewicz, of Görbersdorf, has followed Rosenbusch's method in a few cases. The results he obtained were not so favorable, however. In one of his cases, fever and hæmoptysis followed an injection, and the cough and expectoration increased. Notwithstanding this disappointment, Dr. Stachiewicz is disposed to think that intra-pulmonary injections of creasote may, perhaps, be of service where the cavities are superficial, or where there are hydatids or gangrene of the lung, and he suggests that it may, perhaps, be resorted to in some desperate cases of phthisis as a last resort.

This very temperate endorsement of the method of intra-pulmonary injections, which, as we have said, was first employed in our own country, seems to us quite justified by all the experience which has accumulated in regard to it. Perhaps even more might be said in its favor, and it may, in fact, deserve a place in the therapeutics of phthisis pulmonum in connection with other methods which have come into use with the most recent ideas as to the nature and proper treatment of this disease.

FAITH CURE.

The absurdities and errors of the leaders and disciples of the so-called "Faith Cure" movement have been repeatedly adverted to in medical and secular journals, and it is interesting to find that they are appreciated in theological circles also. In the *Forum*, August, 1888, the Rev. Leonard Woolsey Bacon, D.D.—and M.D. also—has an article entitled "The Faith Cure Delusion," in which, in his trenchant style, he exposes the weakness of the claim these people make, that their belief rests upon a Scriptural basis and is not amenable to the application of usual processes of logical reasoning. Such a claim should at least rest upon a correct citation of Scripture and a reasonable interpretation of it. But, as Dr. Bacon explains, the Faith Cure delusion can show neither the one nor the other. The passage from the Epistle of St. James which is constantly referred to as justifying the claims of Faith Cure is quoted as it appears in the English translation, which does not express the meaning or sense of the original Greek. The most striking defect is in the use of the word "anointing," in translating a Greek word which signifies inunction—the one implying a sacramental procedure, and the other a purely medical operation. An equally important error in the use of this text depends upon a misinterpretation of the injunction to "call for the elders of the Church" in case of sickness. As Dr. Bacon explains, this was an injunction to summon the oldest and most intelligent men in the Church, men wise in the management of cases of sickness, as well as in the comforting of those in religious distress, in order that they might administer at the same time spiritual consolation and medical treatment. The latter, in those days, often began with inunctions with oil, and it was this practice to which the writer of the Epistle plainly refers, since he uses a word which was commonly employed to describe it.

In the light of this rendering and interpretation of the passage referred to, the

claim of Scriptural sanction put forth by the leaders of the Faith Cure movement becomes as absurd as their practice is preposterous. And, even if it were admitted that a literal translation of the expression of St. James might seem to justify a hope that disease might be cured without the intervention of human agencies, the same expectation ought to be held in regard to the satisfying of hunger; for there are in the Bible as distinct promises of relief of the poor and hungry as of the sick. As Dr. Bacon says: "There is positively not one particle more of encouragement there for a 'faith hospital' without physicians or medicines than there is for a faith hotel, with neither kitchen nor victuals nor cooks" Thus it appears that those who cultivate the delusion of Faith Cure have no more warrant in Scripture than they have in medical science or common sense. Meanwhile a patient community tolerates their errors and permits a continuance of their mischievous work. The sick are deceived, weak minds are unhinged, homes are wrecked, and all by persons pretending a desire to do good, and claiming Divine authority for what they are doing. Surely it is time for the law to interfere and to restrain a class of persons who are utterly condemned by the two professions best fitted to judge of the merit of their claims and the effect of their practices.

MILK INSPECTION.

There is one thing which they seem to do pretty well in New York, namely, the inspection of the milk supply. This is due not so much to good laws as to the fact that they are executed by a most efficient and zealous public officer, Dr. R. H. Nevins, who carries out the duties of his office in a way which indicates his appreciation of its importance. One of the measures he adopts to make his inspections fulfill their object is to make sudden and unannounced descents upon milk dealers at the railway stations through which most of the milk supply of New York passes, and then to have the milk in their cans subjected to certain immediate tests by a number of his assistants, and to pour into the gutter the contents of any cans of milk which are below an appointed standard of purity. By this means he reaches more dealers than he can touch; for the fear of an unexpected test must keep many honest who would swerve from the right path if the inspections were made in any other way.

But, valuable as these tests may be, there is one which would, we think, be even more serviceable to the community; this is the inspection of the milk dealt from wagons and so-called milk depots in the poorest parts of large cities. A tour of inspection among the retailers of milk to the poor would, we think, do more to correct the horrible cheating which goes on in this article of food than all the investigations conducted at railway stations. Between the time when a pure milk leaves the inspector at this point, and that in which marasmatic children in the courts or alleys get the thin and spoiled liquid sold for milk, is where honest and intelligent inspectors would be of most service.

The systematic inspection of milk offered for sale is a part of the duty which the Government owes to those who are under its protection, and we wish there might be in every city an authorized corps of inspectors who might come down at any moment upon retailers of articles of food and drink, and hold them to account for what they furnish to their customers. This is the only way—and, if properly carried out, would, we believe, be a sure way—of suppressing the adulteration of food and drink, which is one of the greatest sins of this generation.

—M. R. W. Williams, of Cameron, Clinton County, Missouri, was fined $300 by a local magistrate for dispensing whiskey, although it was done upon the prescription of a physician. The Circuit Court affirmed the judgment of the magistrate, but the Supreme Court of the State has just reversed the decision of the lower court.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

DISEASES OF WOMEN. By Arthur H. N. Lewers, M.D., Lond., M.R.C.P. Lond., Assistant Obstretric Physician to the London Hospital, etc. 8vo, pp. xvi, 400. Philadelphia: P. Blakiston, Son & Co., 1888. Price, $2.25.

This is one of the best hand-books on the subject of diseases of women which we have ever seen. It opens with an admirable account of the way in which one should proceed in determining the nature of the trouble for which a woman seeks relief, and this goes into details in a manner which must prove exceptionably serviceable to those who have—as many medical men unfortunately have—to learn their gynecology without the assistance of personal instruction from masters in the art. After this, the various diseases and disorders peculiar to women are discussed systematically, beginning with disorders of menstruation and ending with nerve-prostration and hysteria. The various operations of gynecology, and the instruments with which they are performed, are well described and fully illustrated, and the details include descriptions of Apostoli's method of treating fibroids of the uterus, and Weir-Mitchell's "rest cure."

It is hard to do justice to a book like this in a limited space, but it is pleasant to be able to recommend such a book strongly to the attention of our readers. Its moderate price places it within the reach of all, and those who buy it will, we think, be as much pleased with its handsome appearance as with the literary and scientific character of its contents.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

Heart and Blood-Vessels in the Young. By A. Jacobi, M.D., New York. From the *Brooklyn Medical Journal*, March, 1888. 19 pages.

The Relations of Mind and Body. By H. R. Hopkins, M.D., Buffalo, N. Y. From *The Medical Press of Western New York*, October, 1887.

An Improved Sphygmograph and its Work. By H. R. Hopkins, M.D., Buffalo, N. Y. From the *Medical Press of Western New York*. 10 pages.

The Ischiatic Crutch. By A. B. Judson, M.D., New York. From the *Medical Record*, June 25, 1887. 8 pages.

—Dr. Jacobi's pamphlet contains the Address delivered before the Association of the Alumni of the Long Island College Hospital, February 27, 1888. It discusses the peculiarities of anatomy and function of the circulatory organs of children as compared with those of the same organs in adults. One of the most interesting features of this discussion is the reference to the methods of the ancients in studying the pulse; and we think it would be well if all medical men showed the same respect which Dr. Jacobi does for the shrewd observations of our predecessors, who, in the absence of such instruments of exact investigation as we possess, cultivated their natural resources to such a wonderful extent.

The whole of this Address is both interesting and instructive, especially as it treats of a subject which has not received as much attention as it deserves.

—Dr. Hopkins's pamphlet contains an Address delivered at the opening of the Forty-second Annual Session of the Medical Department of the University of Buffalo. In this Address, the writer makes an argument against materialism, and in favor of the belief in vital force and the independent existence of mind and soul. His argument is interesting, and the position to which it leads one which is hard to impugn successfully. There is still need for defending it, it is true; but the number of those who scoff at a belief in an immaterial essence in man is by no means so large as it once was, and it is pleasant to find one who speaks with authority to young men, starting them in their medical studies with a warning against the coarse and illogical conclusions of the materialists.

—Dr. Hopkins's paper contains an admirable argument for the use of the sphygmograph as an instrument of precise diagnosis, and a very strong recommendation of the instrument designed and made by Mr. A. M. Edwards, of Buffalo. Dr. Hopkins recognizes the fact that many observers have been disappointed in the use of the sphygmograph; but he attributes this disappointment to the use of imperfect instruments. The Edwards sphygmograph is, in his opinion, so excellent that it does not lead to disappointment, and it has, in his hands, given tracings which are of the greatest value in studying the phenomena of arterial tension. His pamphlet contains, incidentally, a good deal of interesting material in regard to the physiology of arterial tension, amply illustrated, and may be warmly commended to the attention of the readers of the Reporter.

—Dr. Judson's pamphlet describes and illustrates a form of support which he has devised for use in cases of osteitis of the hip or knee-joint, in connection with a high sole on the foot of the sound side. The principles involved in its construction are not new, but the apparatus seems well adapted to its purpose, and it has proved entirely satisfactory in his practice. Its cost is moderate, and, altogether, it seems worthy of the notice of the profession.

Literary Notes.

Littell's Living Age is one of the most welcome visitors to our table. For years it has furnished American readers with the cream of European literature, and those who have become accustomed to its fare could never, we think, give it up unless driven to do so by poverty. "Good wine needs no bush"; and it is hard to find new words as praise for what is so well known and so much admired.

The American edition of the *Illustrated London News* maintains its high standard of contents and illustration. Few weekly publications can compare with this in interest and attractiveness. The contents relate almost exclusively to European affairs and the dependencies of Great Britain; but they have a great deal of instruction in them for our countrymen. The illustrations are unusually fine and very numerous.

CORRESPONDENCE.

Notes on Diphtheria.

TO THE EDITOR.

Sir: Diphtheria is rather an old acquaintance. I treated my first case 34 years ago this month. I hardly knew then what to call it, but it died on time. I have treated it every year since then, with varying success, according to the violence of the particular epidemic.

It has no respect for persons, surroundings, or sanitary conditions: patients in the best being just as liable to die as those in the worst locations. Squalor and filth apparently exert no influence. Diphtheria and croup are not the same. Nineteen out of twenty cases of membranous croup will recover, if properly treated. Diphtheria treated in this way will all die.

It is certainly contagious in the true sense of the word. It can be communicated in all stages; but a convalescent, two weeks after the throat-symptoms have disappeared, is much more likely to communicate it. By far the greater number of cases that I have been able to trace to direct contagion have taken it by playing with such convalescents.

Girls are more liable to contract the disease than boys, and about three girls will die where one boy will, the greater extent of mucous surfaces probably being the reason. The peculiar eruption has been a fatal symptom in every case of it that I have seen; and, when the post-cervical lymphatics are enlarged, feeling under the skin like a handful of flat Lima beans, it is very safe to conclude that you are going to lose the patient, however mild the general symptoms may seem to be. Many children are lost by encouraging or allowing them to get up and play too soon, the heart-muscles not being able to stand any increase in amount of work.

As to treatment, we have none established for the disease. It is easier to find out what does no good than what does. I have heard an intelligent physician say, in our State Medical Society: "The reason that practitioners had such deplorable luck in treating diphtheria was because they did not know how to use quinine, iron, and chlorate of potash." It is probable that he had never seen a case of genuine malignant diphtheria. Experience has taught me not to use arterial sedatives; not to use chlorate of potash, for fear of kidney complication; that iron is useless, and quinine probably worse than useless. I have not given a dose of the latter medicine within the last 10 years, except it would be in a case of doubtful diagnosis in the first stages, and then I have almost invariably had cause to regret it. I am not able to explain just why, but I have been impressed that it exerts an unfavorable effect on the nervous system.

Having been a reader of medical literature, I tried every plausible plan of treating this terrible malady. I have come to the conclusion that remedies must be given with a view to their antiseptic properties. I generally commence with a decided mercurial cathartic, followed by antiseptics, mercurial or other, internally. Hydronaphthol is my favorite; it also keeps the house full of its fumes. Pilocarpine, sufficient to keep the saliva flowing moderately; oil of turpentine internally in teaspoonful to tablespoonful doses, according to age; papoid or trypsin applied to the exudation, both in powder and spray; nux vomica as a nerve tonic, with all the food possible to get them to take, using, with the food, stimulants to aid assimilation. No swabbing or picking at the throat. I have lately seen a case of malignant diphtheria in a child 7 years old recover under the above remedies, the turpentine being given in teaspoonful doses every two hours. I would not have given a penny for his chances when the treatment was commenced, the bronchial tubes being seriously obstructed.

A. ADY, M.D.

Muscatine, Iowa,
June 12, 1888.

NOTES AND COMMENTS.

A Centenarian.

The hundredth birthday of Col. George L. Perkins was celebrated at Norwich, Conn., recently. The old gentleman looks as if he were good for another hundred, is actively engaged in business, walks four miles to his office every day, and is as erect and strong as any man of sixty. When his family physician died, a few years ago, he offered the vacant place to a young doctor, but with the remark that there was some risk in accepting it, as he had buried seven of his doctors already! He is full of reminiscences of the earlier years of the century, one of these being his ride on Robert Fulton's first steamboat on her trial trip. He was nineteen years younger than Napoleon, and was born in the same year with Byron.—*Philadelphia American.*

Hygienic Conditions in Memphis.

Charles Dudley Warner says: Ever since Memphis took itself in hand with a new kind of municipal government, and made itself a healthful city, good fortune of one kind and another seems to have attended it. Abundant water it could get from the river for sewerage purposes, but for other uses either extensive filters were needed or cisterns were resorted to. The city was supplied with water which the stranger would hesitate to drink or bathe in, from Wolf River, a small stream emptying into the Mississippi above the city. But within the year a most important discovery has been made for the health and prosperity of the town. This was the striking, in the depression of the Gayoso Bayou, at a depth of 450 feet, perfectly pure water, at a temperature of about 62°, in abundance, with a head sufficient to bring it in fountains some feet above the level of the ground. Ten wells had been sunk, and the water flowing was estimated at ten millions of gallons daily, or half enough to supply the city. It was expected that with more wells the supply would be sufficient for all purposes, and then Memphis will have drinking-water not excelled in purity by that of any city in the land. It is not to be wondered at that this incalculable good fortune should add buoyancy to the business, and even to the advance in the price, of real estate. The city has widely outgrown its corporate limits, there is activity in building and improvements in all the pleasant suburbs, and, with the new pavements which are in progress, the city will be as attractive as it is prosperous.

Climate is much a matter of taste. The whole area of the alluvial land of the Mississippi has the three requisites for malaria—heat, moisture, and vegetable decomposition. The tendency to this is overcome, in a measure, as the land is thoroughly drained and cultivated. Memphis has a mild winter, long summer, and a considerable portion of the year when the temperature is just about right for enjoyment. In the table of temperature for 1887, I find that the mean was 61.9°, the mean of the highest by months was 84.9°, and the mean lowest was 37.4°. The coldest month was January, when the range of the thermometer was from 72.2° to 4.3°, and the hottest was July, when the range was from 99° to 67.3°. There is a preponderance of fair sunny weather. The record for 1887 was: 157 days of clear, 132 fair, 65 cloudy, 91 days of frost. From this it appears that Memphis has a pretty agreeable climate for those who do not insist upon a good deal of "bracing," and it has a most genial and hospitable society.—*Harper's Magazine*, September, 1888.

Nurses and Nursing.

To fulfill her duty wherever she may find herself, and to give satisfaction to all, a nurse must possess infinite tact and patience, be a rapid observer, and quick to read the characters of those with whom she comes in contact. The cheerfulness which may brighten one patient may be regarded as obtrusive chatter by another; the constant attentions which will soothe one will irritate the next. The nurse who pleases all must indeed be a wonder. It is reported that a celebrated physician remarked to a patient whom a constant succession of nurses had failed to satisfy: "You had better send to heaven, my dear sir, and demand a hospital-trained angel with a cast-iron back." The financial circumstances of these nurses are a little better than those of their hospital sisters, but their duties are every whit as trying. When the doctor lives far away, the responsibility they incur in cases of danger is great, and often their periods of rest are constantly broken by anxious friends. And frequently, when the patient gets better, the nurse is regarded as a nuisance, and her former devotion is forgotten. It is to be regretted that some institutions, which are merely business speculations, choose their nurses with so little discrimination that discreditable specimens are sometimes met with who throw disgrace on the entire community. As a matter of fact, perfection is no more to be found among nurses than other human beings, and yet these women must be sustained by worthy motives to labor so diligently for so scant an earthly reward. It will indeed be a blessing to many to think that the nurses are to have the practical benefit of a charitable scheme, and that the cases of destitution and misery in their ranks, of which every matron has had cognizance, will now be tales of the past. It is these heroic women who find their way into every household, from the castle to the cellar tenement; who, wherever pain and sickness are rife, come with skilful hands and sympathizing hearts to heal and bless. Facing without fear the risk of infection, a nurse will make her home in a fever hospital; or, beside the dying bed of some poor wretch, will risk contagion of an even more fearful nature. These are the women who never bow down to what Mr. Stevenson calls the "bestial goddess of Comfort and Respecta-

bility"; who can perform the most menial services with dignity, and to whom nothing is common or unclean. These are the women who carry, wherever they go, an atmosphere of noble labor and unselfish enterprise which brings to this work-a-day world a gleam of the glory to come. It is the nurse whose purity and truth break through the crust of skepticism with which our souls were crusted over, and open once more the stream of love and faith which flooded our being in our youth. Before the keen light of earnestness in a nurse's eyes, the froth and frivolity of social life dry up to nothing, and in their stead grow noble aspirations. The influence exercised far and wide by a nurse is almost unbounded, and, if she is actuated by the fervent love of humanity which urges many women to undertake this work, she can carry everywhere with her a glorious torch to light all upward toward more sublime and unselfish aims, lifting them for awhile above the trivial commonplaceness of which too many of us are liable to allow our lives to consist.—*Westminster Review.*

Faith Cure.

On August 19, John Elsey, the founder of the Elsey Memorial Chapel and the millionaire fish-dealer in Washington Market, New York, was baptized in Newark Bay. The faithcurists turned out in large number to take part in the service, and seven others were also baptized. While waiting for the flow of the tide, a meeting was held around the little platform Mr. Elsey has had erected in an opening in the woods. Several men and women told their experience. Mr. Elsey spoke about fifteen minutes. He said that by the faith cure he and his wife had been made whole, his son cured of drunkenness, and his daughter of consumption.

Elusive Hydrophobia Germs.

Saul may be said to be among the prophets when the New York *Herald* finds anything incredible or absurd in regard to hydrophobia. But even this has come to pass. The *Herald*, August 8, 1888, published the following amusing and suggestive item, headed "Elusive Hydrophobia Germs. They passed from dog to horse, and the hens barely escaped.

"A valuable horse, owned by the Smith Trucking Company, on Canton Street, near Park Avenue, Brooklyn, was attacked by hydrophobia some weeks ago, and, as mentioned in yesterday's *Herald*, was shot by an officer of the Society for the Prevention of Cruelty to Animals on Monday last. Yesterday it was reported that some chickens had eaten oats that the horse had failed to swallow, and had also gone mad.

"A *Herald* reporter visited the stable on Canton Street yesterday, expecting to find a number of mad chickens; but he was doomed to disappointment, for the chickens were stubborn, and refused to bark like a dog or whine like a horse. They, however, crowed lustily.

"'If they had eaten the oats,' said an employé of the company, 'the results might have been very painful. Now, just see what might have happened, but which, happily, did not: The chickens might have gone mad and then laid a lot of eggs, which would have been eaten by human beings, and thus the persons who ate the eggs might have commenced to crow like chickens, neigh like horses, or bark like dogs.'"

Policeman's Diagnosis of Hydrophobia.

The daily papers state that a policeman found a colored man on last Saturday afternoon, at Seventeenth and Spring Garden Streets, rolling around in the street and frothing at the mouth. Thinking that the man had hydrophobia, he is said to have procured a rope and fastened him to a tree, summoned the patrol wagon and had him removed to the Philadelphia Hospital. It was found that the man was suffering from a severe attack of colic.

Detection of Iodine in the Urine.

Iodine is best detected in the urine by adding to half an ounce of the fluid, in a test-tube, 40 minims of dilute sulphuric acid and 20 minims of chloroform, or of bisulphide of carbon, and, finally, a few drops of a one per cent. solution of sodium nitrite, closing the tube and shaking well. If iodine is present, the chloroform assumes an amethystine tinge. Freshly-made starch paste may be used instead of the chloroform, and will give to the fluid a blue color if iodides are present.—*Pharmaceutical Era*, July, 1888.

Removing Indelible Ink.

Physicians are often asked how to remove indelible ink, and they sometimes cannot quite remember; so we repeat the following method: First moisten the stain with tincture of iodine, and, after a few minutes, remove the iodine stain with solution of hyposulphite of soda. Finally wash in clean water. Repeat if necessary.

The Juniata Valley Medical Association.

The thirteenth annual meeting of the Juniata Valley Medical Association was held August 14, at Cresson.

The Association was presided over by Vice-President Dr. J. P. Sterrett, of Pittsburg, and physicians were present from Harrisburg to Pittsburg. Several new members were elected.

An interesting paper on hygiene was read by Dr. W. F. Bishop, of Harrisburg, which led to a lively and edifying discussion. Dr. Bishop closed with a lucid exposition of the necessity for pure air and water, and plenty of both, for the maintenance of personal and public comfort and health. The most remarkable feature of the meeting was the adoption of the following resolution:

Resolved, That the charges made at the late meeting of the Pennsylvania State Medical Society by the aiders and abettors of a State board of licensers and examiners that the medical colleges of our State are corrupt and venal, and the medical profession of Pennsylvania is in a debased and degraded condition, are false and slanderous, and are hereby publicly and emphatically rebuked.

The Secretary was directed to furnish our Representatives and Senators with a copy of the above resolution, with a request that they oppose the establishment of such a board of examiners and licensers.

American Rhinological Society.

The Sixth Annual Meeting of the American Rhinological Society will be held at the Gibson House, Cincinnati, Ohio, September 12, 13, and 14, 1888. An interesting series of papers and discussions is on the programme. Dr. C. H. Von Klein, Dayton, Ohio, is President; and Dr. John North, Keokuk, Iowa, Secretary and Treasurer.

Mississippi Valley Medical Association.

This Association will meet in Pickwick Theatre, Jefferson and Washington Avenues, in St. Louis, September 25, 26, and 27, 1888, two weeks later than first announced. This date was selected in order that the cheap railway rates during the carnival season in St. Louis might be made available.

For further information, address I. N. Love, M.D., Chairman Committee Arrangements, Lindell and Grand Aves., St. Louis.

NEWS.

—Dr. J. W. Arnold is reported to have been shot and killed by W. J. McMath, near Shreveport, Louisiana, on August 29.

—Professor Gerhardt has been elected Rector Magnificus of the University of Berlin. Dr. Waldeyer is to be Dean of the Faculty.

—Dr. Walter L. Ranney died in New York City, August 17. He was graduated from the University of the City of New York in 1880.

—Paul Langerhaus, formerly Prosector in the University of Freiburg, died of phthisis, in Funchal, Madeira. He was only thirty-nine years old.

—Dr. William Preyer, Professor of Physiology at the University of Jena, and, next to Haeckel, its greatest scientific ornament, intends, it is stated, to resign his position and remove to Berlin.

—Yellow fever is still on the increase in Jacksonville, Fla. Twenty-four new cases of yellow fever and two deaths were reported in Jacksonville, September 1. The total number of cases up to that time was 258; total number of deaths, 34.

—The Trustees of the Ohio State College have elected Professor David S. Kellicott, of Buffalo, to the Chair of Zoology and Comparative Anatomy, the position made vacant by Professor A. H. Tuttle, who goes to the University of Virginia.

—Mr. Lawson Tait, the distinguished surgeon, of Birmingham, England, writes to a friend in this city that he will not be able to attend the Congress of American Physicians and Surgeons, to be held in Washington during this month.

—The *Lancet*, August 18, 1888, announces that Sir Morell Mackenzie's reply to the charges of the German physicians will soon be issued simultaneously in German and English. The English edition will be published by Messrs. Sampson, Low, Marston & Co.

—Dr. Joseph Moore, of Bridgeton, was struck by a train near Bridgeton, September 1, and injured so badly that he died soon afterward. He was driving in his carriage, when the horse became unmanageable and sprang in front of the train. The Doctor was thrown several feet in the air, and fell on his head.

—A Connecticut physician has stated his belief that fresh air, especially at night, is a necessity in the treatment of cholera infantum. The New Haven *News* adds that

lately it has not been uncommon to see a baby-carriage, containing a little sufferer, wheeled by a devoted parent all night long on Fair Haven Heights.

—The *Chemist and Druggist*, August 11, 1888, says that one of the latest uses of saccharin is as an addition to whiskey in place of liqueurs. One-quarter ounce suffices for a hogshead of whiskey, and it is said that it immediately increases the value of the article by exerting a maturing influence upon the spirits. It is certain, at least, that it mellows the flavor of the spirits considerably.

HUMOR.

HE IS A FORTUNATE doctor, says the Philadelphia *Ledger*, who can let off bulletins without feeling their recoil.

THE MAN WHO SAYS he will welcome death as a release from a life made up of sorrow, generally sends for four doctors when he has the colic.

BETTER THAN A BURIAL—Cholly: "I say, Binx, did you ever witness a burial at sea?" Binx: "No, never saw a burial, but we had a wake all the way over, last trip."—*Harper's Bazar.*

A: "WHAT DENTIST made your teeth for you?" B: "These are my own teeth. No dentist made them." "You don't say so! How deceptive they are! Why, they look as nice as the best kind of false teeth. What a wonderful thing nature is."

MAMMA: "Did you have a nice time at the party, Harry?" Harry: "Oh, yes, splendid! I had five kinds of cake. First I had some sponge-cake and chocolate-cake, and then I had jelly-cake and cream-cake, and then I had the stomach-cake."

A HANDSOME PROFIT.—Aunt Emily: "Why do you think you will be a doctor, Bobby, when you grow up?" Bobby: "Because I swallowed a ten-cent piece the other day, and the doctor charged pa two dollars for curing me. That's a good business."—*Epoch.*

ABOUT SEVEN YEARS AGO, George W. Mitchell, of Palatka, Fla., falling against a cactus-plant, one of its thorns entered the calf of his leg. Several weeks later, the thorn was withdrawn from a swelling on his chin. This story is a welcome change from the old newspaper item about a girl running a needle into her thumb, which caused her no pain until six years subsequently, when it was removed from the ankle of her brother-in-law; but it is about as hard on a man's credulity.

OBITUARY.

RANDOLPH S. HITTELL, M.D.

Dr. Randolph S. Hittell, of Argentine, Kansas, a graduate of the Jefferson Medical College, Class of 1870, died March 9, 1888, aged 37 years. By his death the profession lost one of its best surgeons in the Southwest. He was a native of Allentown, Pennsylvania. He was Assistant Surgeon in the Prussian Army during the Franco-Prussian War of 1870–'71. After the war, he returned to Philadelphia, where he practiced medicine for about two years, when he removed to the West, and he became noted as one of the finest surgeons of the country. The cause of his death was typhoid fever.

JAMES SUDDARDS, M.D.

Medical Inspector James Suddards, U.S.N., died at Atlantic City, N. J., August 31. He was graduated from the University of Pennsylvania in 1847. Dr. Suddards entered the United States Navy, May 17, 1849, when he was commissioned an Assistant Surgeon, from which position he was advanced, in April, 1861, to Surgeon. On March 3, 1871, he became Medical Inspector, and, on April 5, 1875, he was made Medical Director. At the time of his death, he was President of the Medical Examining Board, to which he was appointed on April 22, 1884.

THOMAS T. SABINE, M.D.

Dr. Thomas T. Sabine, Professor of Anatomy in the College of Physicians and Surgeons, New York, died August 23 He was graduated from the College of Physicians and Surgeons in 1864, and subsequently served on the house staff of the New York Hospital. While in this position, he showed signs of lung-disease, and subsequently developed marked disease of the lung, which eventually proved fatal.

R. H. MILNER, M.D.

Dr. R. H. Milner, of Chester, Penna., shot himself, near Crum Lynne Station, August 29, 1888. He had been a sufferer with lung-disease for some time before his death, and, for several days during the week before his death, was confined to bed.

He was 47 years old, and was graduated from the Medical Department of the University of Pennsylvania in 1868. Dr. Milner was held in the highest esteem by his neighbors and professional associates. The disease from which he suffered is said to have been contracted during the late war. He leaves only one child, a daughter five years old. His wife died three years ago.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

Prof. Alfred Stillé, Prof. Wm. Goodell, Prof. D. Hayes Agnew, Prof. H. C. Wood, Prof. R. A. F. Penrose, Prof. Wm. Pepper, University of Pennsylvania, Prof. J. M. DaCosta, Prof. Roberts Bartholow, Jefferson Medical College, Prof. Chas. K. Mills, Philadelphia Polyclinic.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,
36th and Woodland Ave., Phila.

W. H. WALMSLEY & CO.

SUCCESSORS TO R. & J. BECK,

No. 1016 Chestnut Street, Philadelphia, Pa.

Microscopes,

Microscope Accessories,

Mounting Materials,

Dissecting Instruments,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

THE

College of Physicians and Surgeons

OF CHICAGO.

Seventh Regular Session opens Sept. 25, 1888.

GRADED COURSE OF INSTRUCTION.

Unsurpassed Clinical Advantages.

FEES.—Matriculation, $5; General Ticket, admitting to all the lectures and including all practical work in the Laboratories, $60. For announcements and further information, address

LAPAROTOMY WITH EXCISION OF A PORTION OF THE ILEUM.

BY D. HAYES AGNEW, M.D.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

A large fleshy woman was admitted into the University Hospital, suffering from strangulated umbilical hernia. The tumor was one of considerable magnitude, and had existed for several years, the contents being only partially reducible. She had been seen by two excellent physicians, Drs. Smock and Hughes, before her admission, who had applied the taxis, but without success. When examined by me, the swelling was resonant and flat at different points on percussion, revealing the mixed character of its contents—that is, both intestinal and omental. The vomiting was severe, stercoraceous in character, with threatening collapse of the system. After etherization, a few minutes were employed in a renewal of taxis, but without any favorable result, when a resort was at once had to herniotomy. The overlying layers of tissue being incised, the seat of stricture was sought for at the upper angle of the wound, detected, and divided. The intestine was found to be inky black, and oozing from its surface was a bloody serum. The omentum was greatly thickened by interstitial deposits, by long residence outside of the abdomen, and was really unfitted for being replaced. After waiting a short time to see if the relief of the constriction would change the appearance of the contents, and finding no alteration, I removed the mass of omentum, and exsected fourteen inches of the disorganized bowel with a corresponding part of the mesentery, divided in a V-shaped manner. The vessels being carefully tied, the cut ends of the intestine were now brought together, and united by a series of Lembert silk sutures, extending round the entire circumference of the wound, and placed at a distance less than one-eighth of an inch apart; the depth of penetration of the stitches reached only to the mucous coat. The intestine was now returned into the abdomen, and the parietes closed by a number of interrupted sutures. The entire procedure was done under strict antiseptic methods. Though considerably shocked by the conjoined effects of the disease and the laparotomy, yet the woman reacted satisfactorily, and, in the evening of the day, was quite comfortable. On the afternoon of the following day, she was attacked by nausea and vomiting, threw up a large quantity of blood, and died.

At the autopsy, the ends of the intestine were found fairly well united, except at one point on the mesenteric surface, where one of the stitches had torn out, though no escape of fecal matter was discovered to have occurred. The source of the blood vomited was supposed to have come from the vessels at the seat of operation.

With the light daily accumulating in this department of surgery, it would have been better, instead of stitching together the ends of the intestine, to have brought them out of the external wound and to have attached the half circumference of each to the parietes, preparatory to another and a later operation for re-establishing the continuity of the intestinal canal. The time required for similar operations might be considerably

shortened by adopting the suggestion of a writer, whose name I cannot at this moment recall, viz: Instead of excising the V-shaped piece of the mesentery, to double the redundant portion of that structure on itself, keeping the two layers in contact by properly inserted stitches, and thus converting the two layers into one by an intermediate bond of lymph.

EARLY OVARIOTOMY.

BY R. S. SUTTON, M.D.,
SURGEON TO TERRACE BANK HOSPITAL FOR WOMEN, PITTSBURGH, PA.

In an able editorial in the MEDICAL AND SURGICAL REPORTER of August 11, 1888, the following paragraph occurs: "Dr. Sutton, in the REPORTER of June 2, 1888, forcibly insists upon this point (early ovariotomy); but, from the illustrative case which he reports, it might be inferred that the advantages consist in the ease and rapidity with which the operation can be done. A short operation unquestionably favors recovery, not only by the less amount of shock experienced, but by the smaller number of germs which gain access to the peritoneal cavity. Adhesions are much less apt to be encountered in cases operated upon early than in those in which operation has been deferred."

The first and second points—a short operation favors recovery and the less danger of encountering adhesions—are well taken and patent to every reader. But that a short operation is especially advantageous by reason that a smaller number of germs gain access to the peritoneal cavity is questionable, and not in accordance with my experience. Prior to 1881, like many of my countrymen, I was a disciple of Lister. After nearly two years' experience in the clinics of Europe, and long attendance upon the operations, public and private, of Keith, Tait, and Bantock, my faith in Listerism was broken. Nevertheless, it was a difficult matter to get rid of preconceived ideas upon the subject. At a meeting of the American Gynæcological Society, held after my return from Europe, in the autumn of 1883, I read a paper entitled "Cleanliness in Surgical Operations," from which I repeat the following extracts: "Listerism seemed to be just the thing we all needed, and it was almost universally adopted. The object of this method was to destroy these germs, these micrococci, and these bacteria. But the microscope kept on keeping watch over the result, and detected micrococci under the Lister dressings of carbolic acid; yet these wounds healed faultlessly—no pus, no inflammation. Further, living micrococci were found in 5 per cent. solutions of carbolic acid. Two things were now patent—that the presence of all micrococci in wounds did not prevent faultless healing, and that even a 5 per cent. solution of carbolic acid did not in a short time destroy all micrococci. The assertion that the germ theory was not entirely correct was now made; and further, that the antiseptic method failed to destroy all germs."

"Doubts once initiated, a war of arguments and statistics followed, and it was proved, if ever anything was proved, that surgery under Listerism, either entire or modified, was better than it had ever been before.

"The whole argument was based on the supposition that Listerism was carbolic acid, and carbolic acid Listerism. They seemed to forget the great details of cleanliness which the antiseptic method carried with it. They forgot the importance of wet instruments. The believers lauded Mr. Lister and carbolic acid *ad astra*. A few men, practical surgeons, ventured to experiment with Listerism. One, the late Professor von Bruns, ceased using the spray and substituted irrigation; the result was his celebrated enunciation: '*Fort mit der Spray.*' Dr. Thomas Keith had done so well with Listerism in ovariotomy that his results were looked upon as an overwhelming argument in favor of the germ theory of Pasteur and the germicide method of Mr. Lister. But Dr. Keith had this secret: septic poisoning had occurred in his cases in spite of Listerism. Moreover, he believed that one or two of his patients had died from carbolic-acid poisoning In this view he was sustained by his able friend, Professor Hamilton, pathologist at Aberdeen. Dr. Keith dropped the spray, and proved, by one hundred cases of ovariotomy done without it, that his results were better than in one hundred cases done under it. Dr. Bantock systematically reduced the carbolic acid in the spray until he used only pure water; his results were lower temperatures after operations, and more favorable recoveries. As a result, he gave up the use of carbolic acid, both in the spray and in the pans. Mr. Lawson Tait fell into line with his Scotch colleagues, Keith and Bantock, and led the charge against the entire carbolic system; and these three great men have, so far as abdominal surgery goes, proved the worthlessness of the carbolic-acid-spray

feature of Listerism. All the details of cleanliness attached to the antiseptic method they believe in. Three things were now proved, viz.:

"1. All germs are not deleterious.

"2. Carbolic acid in five per cent. solution does not kill all germs.

"3. That the antiseptic method in abdominal surgery admits, with advantage, of modification."

"But, in matters of cleanliness, let every surgeon learn to be methodical and critical. He must keep always before him the fact that no system of antiseptics will cover dirty and slovenly surgery. There are many surgeons who now no longer use Listerism; but there is no successful surgeon of my acquaintance who neglects measures to insure cleanliness.

"All vessels used about operations should consist of glass or porcelain. Glass, by reason of its transparency, is the better. Porcelain, by reason of its pure white color, stands next. Next to these, brass forms the best material, as it admits of rough usage and can be scoured clean. The water used is better to be first boiled, and, if necessary, subsequently filtered. If the water-supply is from a dirty stream, care should be taken. Distilled water can be largely used when it can be distilled from the hospital machinery. For irrigation, cleansing of sponges and instruments, it may be carbolized. When it is possible in the operating-room, large tanks of pure water—medicated or not, as the operator desires—will be found advantageous. With tube and stop-cock, the supply of water is always ready and within perfect and easy control. Sponges are dangerous in surgery. Their innumerable crevices render them good receptacles for dirt of all sorts, solid or liquid or gaseous. They should never, after being prepared for an operation, lie about uncovered. After operation, it is not safe to trust the cleansing process to either a nurse or assistant. The surgeon should take care of his own sponges. Towels may be substituted for sponges. Kœberlé has not used a sponge in intra-abdominal work for nine years. Instruments should never be permitted to dry after being used until they are washed and dried by the attendants. Dry blood or pus is difficult of removal, and stains, suspicious at least, often remain behind. During an operation, they should be handled only by the operator and one person, who gives and takes them from him. The same may be said of ligatures and needles. If sponges are used, the fewer hands they pass through the better. And all such exhibitions as a relay of nurses and assistants standing about warming sponges in their hands until called for is unsafe, untidy, and suggestive of a poor surgeon. After an operation, all instruments should be thoroughly cleansed; every pincet-point and every needle-eye should pass through a spirit-flame. Prior to the next operation, all the instruments should be again cleansed and scalded. Ligatures should be kept on reels, and always be submerged in an antiseptic fluid—five per cent. carbolic acid; or, prior to being used, be well scalded. Silk thus treated may always be left in the tissues. Boiling it for an hour, with or without carbolic acid in the water, renders it perfect for all purposes. No other ligature is any better, and none good is so cheap. Assistants should be impressed with the necessity of having clean clothing and clean hands, and it is always well for both operator, assistants, and nurses to wash their hands and forearms well in turpentine, and afterward in a solution of washing-soda. A basin of clean, warm, carbolized water should stand by the side of the operator, in which he may at any time rinse off his hands.

"No hospital assistant is a safe man if he is careless personally or permits those under him to be so.

"From all intra-abdominal operations, menstruating nurses should be excluded, and all nurses present should be scrupulously clean as to hands and clothing. They should receive sponges from the operator and his assistant only upon plates, and convey them thus to and from the nurse who washes them. All surgical dressings should be kept in covered glass jars or tight tin cans, and never be exposed unnecessarily, and they should be in the care of one person accountable for their condition. Absolute cleanliness of a patient's apartments and bed is a long-established necessity. When the operation is intra-peritoneal, greater safety will be found in as few assistants and spectators as possible.

"On the continent of Europe, Listerism, and the cleanliness accompanying, is seen everywhere. It is modified as to spray by some operators. Thus, Billroth drops the latter during operation; so with Langenbeck and Volkmann. They all use irrigation extensively. Nussbaum, Schröder, Küster, and Martin are Listerists.

"The most careful antiseptic surgeon in Europe is Esmarch. He uses both spray and irrigation, and the peat dressing and decalcified bone drains of Neuber, his first assistant. The spray in Esmarch's clinic is

produced by a current of air instead of steam. Drainage is carried out carefully everywhere. With Esmarch and Neuber, the decalcified bone drain is used; with others, glass and rubber tubes. To secure freedom from infection, the tubes are kept, until used, in carbolized solutions."

Within one year after writing the above, carbolic acid was absolutely banished from all my intra-abdominal operations, and has remained so. Nor has any germicide been substituted in the sponge-water or instrument-bath. I had learned that carbolic acid produced congestion of the kidneys and higher temperatures, and that the patients did better without it. Moreover, I had seen ligatures boiled in a 5 per cent. solution of carbolic acid and placed upon the pedicle, and their application afterward followed by suppuration and then discharge through the abdominal wound.

Mr. Lawson Tait's experience I here append; a portion of his address before the Surgical Society of Ireland.

"1. The use of the spray, which I looked upon as by far the most important, since it covered the whole time of the operation, was absolutely consistent with the theory of the system, and seemed to me, from that point of view, of infinitely greater importance than all the other details put together.

"2. The preparation of sponges, ligatures, instruments, etc., previous to the operation.

"3. Details of occurrence during the operation, such as washing out the peritoneal cavity, etc.

"As carbolic acid is the substance to which Mr. Lister has consistently adhered throughout the whole of his work, and as it is that of almost universal acceptance, my remarks are to be taken as applying solely to it. I found, previous to this research, that the substance thymol, introduced by Mr. Spencer Wells, was too dangerous to be used, and the results of my research have seemed to me too conclusive to have any need for further experiment.

"In order to secure the complete performance of my research, I went to very great trouble about the apparatus, especially about the spray-producer. I had a very large one constructed, which would produce a continuous jet of spray six feet long, and having a base of nearly four feet in diameter, and this could be continuously maintained for about three hours. The spray used at first was from a solution of one in twenty, then one in thirty, then one in fifty, then one in eighty, then one in a hundred. I then tried one in a thousand, and after that I went on with a spray consisting of nothing but steam and common tap-water, and my patients recovered as satisfactorily without the carbolic spray as with it; in fact, I may say that they recovered better without the carbolic acid, for, whilst using that substance in a strong spray, I had several indications of carbolic poisoning, and I very nearly lost one case. This was in the instance of a child, upon whom I operated for pelvic abscess under a spray of one in thirty. Within a few hours after the operation, her urine became quite black from indican, and loaded with albumen. She became unconscious, and finally had severe convulsions. Within forty-eight hours all these symptoms passed off, and she made a perfect recovery.

"At the beginning of my research, I had all my instruments completely covered in baths filled with a solution of carbolic acid—one in twenty—my sponges carefully cleansed and similarly covered, my ligatures scalded and soaked in the same solution for many hours before the operation, my hands and arms and those of my assistant carefully washed and rubbed over with the solution, and every preliminary detail most carefully carried out.

"Then, as with the spray, I slowly and at intervals reduced the strength of the solution, and finally I went through all the performances entirely without carbolic acid. In the same way with the details which came into use during the performance of the operation. Thus I used to sponge out the cavity of the abdomen with a solution of one in twenty, but now I use only tepid water, without carbolic acid at all; and, in cases where there is troublesome bleeding from separated adhesions, I pack the cavity with sponges—as many as twenty at a time—without any carbolic acid in them; or I wash out the cavity with two or three buckets of warm water poured in from a ewer, utterly regardless of germs in either air or water.

"This research occupied nearly two years, and all through that time I was carefully on the watch for either symptoms or results which would arrest me in my experiment, and show me that I was in error, and that I must retrace my steps and re-establish Listerism in my practice. But I found none, and, as all the details of my practice, up to the first of November last, have been published, I need not weary you with them now. Suffice it to say that, since the time when I may be said to have abandoned the practice of

Listerism, I have performed 107 completed operations for the removal of ovarian tumors; and of these there have been only three deaths, or a mortality of 2.8 per cent., besides a large number of other operations for removal of diseased ovaries and tubes, peritoneal and hepatic hydatids, tumors of the uterus and kidney—these having a mortality quite as satisfactory, and a success which has already attracted a wide attention.

"The only survivals of the Listerian method which I retain are the instrument and ligature baths. I keep all my instruments in baths of plain cold tap-water; and I scald all my ligatures in boiling water, before the operation, to get the gum out, and then keep them in cold water. You may ask Why do I keep to this? And I really can say nothing more than that I like to handle the things wet, and I think it prevents the formation of loose blood-clots. There certainly can be no question of germs about it, for the water must contain them in abundance; and I make not the slightest effort to destroy those I believe to be in the air.

"The conclusions I make, therefore, from my research are (1) that the germs which produce the putrefactive changes in dead tissue are harmless when admitted to the peritoneal cavity in the operations such as I perform upon it. The fatal cases of ovariotomy which I have seen since I gave up the use of carbolic acid—three in one hundred and seven operations—were due to the same cause, the production of heart-clot in cases which had been repeatedly tapped; and I believe that, if I were (not?) called upon to operate on cases which had been tapped, my mortality after ovariotomy would almost entirely disappear.

"2. The further conclusions are that none of the Listerian details, nor the system which they constitute in the aggregate, are at all necessary for the proper and safe performance of operations on the abdominal cavity; and that, on the whole, better, and even more, recoveries are made when no carbolic acid is used at all.

"At the International Medical Congress, after the evidence of Dr. Keith and myself upon the matter of the spray, Mr. Lister is reported to have said that possibly in ovariotomy the spray is not necessary. If this is to be accepted as the last utterances of antiseptic philosophy, I can only regard it as another illustration of its marvelous mutability.

"Not six months ago, ovariotomy was quoted as the chief and greatest illustration of the wonders of Listerism; but it happens to be the only surgical area upon which a strict statistical inquiry can be made; and, when that is done, Listerism is found absolutely wanting. If germs are so potent in the case of a lumbar abscess, why do they prove so harmless in my cases of suppurating hæmatocele? If the serous cavity of the knee-joint is so susceptible to septic influences, how does the peritoneum escape? If you cannot remove a cyst of the back without the spray, how do I manage to do without it for a cyst of the belly? If Listerism is essential in removing a piece of dead bone, how is it I can freely dispense with it in removing a slough from the middle of the liver?

"I cannot pretend to answer these questions; they are for Mr. Lister and his disciples. All I can say is, that I do not think they can be answered upon the ground of the antiseptic theory.

"My own explanation of my success is in the direction of accumulated experience and an infinite care over every detail; and I am quite prepared to admit, and I have frequently admitted, that in this direction Mr. Lister's details have done a great deal of good. It yet remains to be proved whether or not an equal success might not be obtained for a series of amputations or excisions, if they were conducted, as my research was, by all the Listerian details being carried out with plain tap-water.

"I do not know, Mr. President, if my remarks fall upon my audience with anything like convincing force; but I am sure you will give me credit for the sincerity of my conclusions, and a desire that they should be dealt with at least as a tentative, perhaps a suggestive, effort.

"Nothing in surgery is final; and, even if the antiseptic theory and practice are all that is claimed for them, I can only urge that we have not yet got to the end of our tether, and that we have a great deal more to learn.

"What you may get out of my paper, I cannot say; but I have had at least this, an excuse for having one of my greatest treats—a visit to Dublin."

Dr. Bantock closes his admirable paper on "Hyperpyrexia after Listerian Ovariotomy" in the following words:

"It only remains for me to add that I have now proved that the claim that has been set up for Listerism cannot be sustained (in preventing pyrexia after operations); that carbolic acid may be introduced

into the circulation in poisonous quantity by means of this method; that when so introduced it manifests its presence by producing a state of hyperpyrexia, and that thus it actually produces too often what it was intended to prevent. And the practical result of all this, so far as I am personally concerned, is that, to meet the evil which to me is so formidable, I have gradually diluted my spray and solutions so as to reduce the whole question to one of *cleanliness*, which, after all, is the true secret and merit of Listerism, and I am happy to say with the effect of very greatly adding to the success of my ovariotomy work."

In a paper entitled "On Ovariotomy," by Dr. Thomas Keith, reprinted from the *American Practitioner*, and kindly sent me by my friend Dr. David Yandell, of Kentucky, I find the following remarks:

"At first our greatest success was with the weak solutions. Toward the end, we got to using the regular solution we use in everything—the five per cent. solution. I had not used this very long when I began to notice that the cases went on quite differently from what they had done before. The night after the operation, we had very often high temperature—104°, 105°, 106°, and once 107°. We had never had anything like that without antiseptics. In the entire two hundred and thirty cases I have referred to, in only two did the temperature rise to 103° the first night, and it never went to 104°, 105°, or 107°. I noticed the difference, and wondered how it could be. I did not then think it was the absorption of the carbolic acid that did it, but I know now that it was. It was after seeing a paper by Bantock that that occurred to me. When I began operating in the theatre at the infirmary, I used the solution strong (Lister's strength), and frequently we had high temperatures in simple cases. In the first case, which was a simple case without adhesions, the temperature rose to 105° the first night. This was clearly traceable to the absorption of the carbolic acid. Then we began to have this rise frequently; so that there was a sort of general order left with the nurses to put on the ice-bag when the temperature rose to 103°, and often, on the first morning after operation when I came in, the ice-bag would be on. We had never had occasion to do this before. I recollect a nurse who had nursed about two hundred cases, had a patient one day with a high temperature, and I sent along some ice and an ice-bag, and she returned word that she did not know how to use them. I had forgotten that she had never had to do with a high temperature. There is no doubt the carbolic acid raised the temperature the first night."

The first thing in Listerism to get its death-blow was the carbolic spray. Now, it went because it was either more dangerous than the germs in the atmosphere, or these germs were harmless The latter proposition is always true, unless the operation is undertaken in an apartment recently poisoned by some infectious disease. And, in the event of the necessity arising to operate in such an apartment, it should be thoroughly disinfected with burning sulphur, and the patient should be spared the dangers of carbolic acid. Says Keith in the same article:

"Since I gave up the spray, I have not had any high temperatures—never anything like 103° in any case; seldom, indeed, has the temperature gone above 100°. The nurses were astonished at its not rising. I have put an ice-bag on but once since I quit the spray.

"I keep the sponges warm. Of course, I disinfect them in carbolic acid. After the first wash in soda and hot water, they are put into a one-in-twenty solution just before the operation. This is then washed out, and they are put into a solution of one in forty or sixty. Sometimes, however, it should be said, I put them in hot water alone.

"I use ligatures of silk and catgut—catgut for simple things. When I tie the pedicle, it is always with silk. I do not like to do it with catgut. I prepare my own catgut, because in getting it from the makers it is often rotten.

"For the external wound, I use silk for the deep sutures, and horsehair for the superficial sutures. I close the wound as perfectly as I can—as close as if it were a wound on the face. I do not look at it for a week, generally. It is then healed.

"I cover it with carbolized gauze, softened with glycerine, about one in eight, and over that a layer of cotton wool and a flannel bandage.

"I drain more cases now than when I operated under antiseptics. I became just a little timid, because it was an awkward thing giving up the spray."

Enough has now been said to prove that I have but little fear of the entrance of air into the peritoneal cavity. I aim at absolute cleanliness, and believe that, with the excellent hygienic surroundings of my private hospital, and with nurses long accustomed to making preparations for abdominal operations, and a growing experience in operating, that the safety of our patients is con-

served by keeping all chemicals out of their abdomens.

I have seen cases with long incisions, and protracted operations, when left dry and clean, make good recoveries. I have seen a pint of pus escape into the cavity of the peritoneum, and, after being well washed out with simple water, fail to produce a peritonitis. I have had the cavity full of gas from the intestines, and no harm come of it, and no chemical was used. The operator who succeeds best in tying all bleeding points, in washing out the cavity with clean water, and in judiciously using the drainage-tube, will, as a rule, obtain the best results possible. But the great plea for early ovariotomy, excepting in cases of intraligamentous cyst, is the avoidance of long incisions, perplexing adhesions, and the ruining of the health of the patient through the enormous growth of the tumor, or its possible malignancy or subsequent degeneration. Added to this are the dangers of accidents, among which are intestinal obstruction, the bursting of cysts, peritonitis, local or diffused, loss of blood into the cysts, twisting of the pedicle, gangrene or suppuration, and finally the possibility of pregnancy ensuing in the presence of a cyst.

After more than a dozen years of experience and study of these cases, I have yet to see the first woman die when the operation was done before she had been tapped.

The great advantage of early ovariotomy is a prompt and early recovery without damage to the woman.

419 Penn Avenue.

THE PREVENTION OF EAR-DISEASE BY CARE IN CHILDHOOD.

BY LOUIS J. LAUTENBACH, M.D., Ph.D.,
ASSISTANT SURGEON TO THE PENNSYLVANIA EYE AND EAR INFIRMARY.

I begin with an obvious fact—the great value of perfect hearing, which, however, is rarely appreciated until it is lost or impaired. One then often suffers intensely, both mentally as well as physically. The frequent misunderstandings and embarrassments to which he is exposed are so discouraging and distressing that he withdraws into himself, and is considered stupid, and possibly finally becomes so. In fact, few physical defects are so powerful in curtailing a man's sphere of action. Numbers come to me feeling the incipiency of this trouble, unconscious as to its causes, which, however, prove to be such as are very simple and easily avoided. It is truly remarkable, when we consider how careless we are with our ears, that they are not more frequently defective. They are being continually exposed without a thought as to their care. This systematic neglect makes it all the more important that the causes of ear-trouble should be appreciated, so that something may be accomplished as to their prevention.

It is especially by proper care in childhood that much of the prevalent ear-disease and consequent deafness is to be avoided; for very frequently the foundation of the trouble is laid in childhood. In children, this organ is in its developing state, and is, in consequence, more liable to disease. This special liability makes it incumbent upon the family physician to acquaint himself with its condition in case anything should occur likely to involve it. It is at this period of life that very serious and chronic ear-troubles begin, troubles which may last throughout life, and be of permanent injury to the hearing. Even though it should not prove to be so severe, yet often at the threshold of manhood there is a consciousness of some deficiency—something restricts the possibilities and forms an additional obstacle in life's encounter. Again, we have slighter cases, which are yet very important. Where the tendency to ear-trouble has been created, the slightest indiscretion is followed by disturbance. It is peculiarly important that the methods of prevention should be impressed upon the family by the general practitioner, as evil results, with the often long and difficult treatment, are thereby avoided. If adult life is reached, and the ears are perfectly sound, we are fortunate, as with ordinary precautions they can almost invariably be kept so.

This paper was designed to call attention to the frequent neglect of the ears of children, when most of the preventive work must be done. Its truths are, however, applicable to all; in fact, it seemed an advantage to make it as general as possible, with the hope that more practical thought would be given to this often neglected branch of preventive medicine.

Poor general health is one of the most important factors in the causation of these cases, and is to be avoided, not for the sake of the ear alone, but for the good of every part of the body.

Colds are the most frequent of the causes of ear-disease. While many cases are occasioned directly by exposure to cold, in by far the majority of cases cold acts by first affecting the throat and nose. As soon as such a catarrh occurs, it is to be treated,

as otherwise it may affect the Eustachian tube and ear. Thickenings and chronic inflammations of the throat and nose almost invariably affect the ears, and require continued care. Should the ears become involved, they should be immediately treated to prevent advancement of the disease. Baring the head when perspiring is an especially common cause of ear-trouble. The hurry to the theatre or to board a car is often the occasion for this among men: the hat being removed either from necessity or for comfort, a slight draught accomplishes the result. A skull-cap would have prevented this. Even the somewhat frequent occurrence of having the hair cut much too close and the whiskers removed is often followed by inconvenience of this kind. When this occurs, the skin is to be washed with alum solution, and afterward well rubbed with a vegetable oil. The vigorous use of a fan is to be discontinued as soon as there is a feeling of stiffness of the neck, or pain or coolness in the mastoid region.

Wet feet, which so often occasion colds, are to be avoided by the use of stout shoes or by wearing good overshoes. The wet ankles obtained by women in rainy weather are to be prevented by having an impervious overdress reaching below the ankles, about two inches longer than the skirts, and by wearing, in addition, water-proof leggings.

Whenever we are liable, while perspiring, to be subjected to draughts of cold air, the wearing of woolens next to the skin is essential to prevention. Sleeping exposed to a draught from open windows or doors, and sudden changes of temperature during the night, is to be guarded against by having an extra blanket or quilt at the foot of the bed.

The low-neck and no-sleeve dress of women should be mentioned in this connection, and it is obvious at once how much harm it can occasion. Women, accustomed to ordinary apparel during the day, undress the upper part of the body for the evening hours, and it is rare indeed that some harm is not done. This mode of dress should be discontinued. The evening-dress of men, while by no means so frequently the cause of ear-trouble, must yet bear its share of blame. When it is worn, it should be over an extra or thicker undergarment.

Driving, by rapidly cooling the body, is sometimes the cause of ear-trouble. The driving-dress should invariably be heavier than the walking-dress. After public speaking or singing, upon going into the open air, a muffler or other neck-cover should be used to prevent evaporation from the neck region. In winter, extra precautions to avoid cooling the neck and mastoid regions are necessary. A muffler or cape is often of value.

Thus far, draughts or exposure of some kind, causing colds, have been mentioned, and for the most part they can be avoided. When colds are present, it is necessary to realize their gravity. During the fevers of childhood, especially scarlet fever, measles, and diphtheria, the attendant inflammation of the throat is usually followed by either actual ear-disease or by weakness and liability to such disease. It is these diseases which give us the most severe of our cases—cases of deafness and very poor hearing, as well as of great destruction of the soft and bony structures of the ear. Much can be done in these fevers to ward off ear-trouble by proper treatment of the throat, the frequent cleansing of the nostrils and the supporting of the physical health; if this is not thoroughly attended to, trouble with the ear will be experienced. Careful prompt treatment will frequently prevent ear-disease and loss of hearing.

Syphilis is quite a frequent cause of ear-disease; patients suffering with it should be told of the necessity of great care. On the slightest evidence of any trouble with their ears, they should consult a physician. Tuberculosis is also a not infrequent cause, but, though by attention to the general health much can often be done to ward off ear-trouble, yet very frequently the ears will become affected.

Ears should be cleansed but rarely, and then with care. Hair-pins should never be used for this purpose; even ear-spoons frequently do harm. Cleansing of the meatus by water should be discountenanced, as the water remains in the ear and often occasions mischief; but, if it is used, the ear should afterward be thoroughly dried. Ear-cleansing is usually not necessary, as nature has, by the gradual expulsion of the wax, made the necessary provision for this. When nature fails, the physician alone should do the cleansing, and remove the accumulated wax.

Swimmers, to avoid the entrance of water, as well as of other foreign bodies, into the meatus, should put cotton in the ear. In addition, they should, when leaving the water, open the Eustachian tube by the effort at forcible inspiration, with the mouth and nose closed, and then, after lightly blowing the nose, force air into these tubes.

The blowing of the nose violently, especially when there is an acute catarrh of the throat or nose, is to be avoided. Proper cleansing of the nose is always valuable.

In this connection, it may be stated that among the most important preventations of ear-trouble is the keeping of the nasal passages perfectly free and clean. This cleanliness of the nose is rarely impressed upon children, but it cannot be too carefully observed. Foreign bodies that may be in the external canal should be removed at the earliest moment.

The long-continued subjection of the ear to high and shrill musical notes is often harmful to it. Brass instruments, emitting high notes, are the most to be feared; but the continual repetition of high notes, as in scale-practicing on the piano, is not invariably harmless. When practicing of this sort is necessary, it should be abandoned when sensations of fulness or of buzzing appear in the ear; but, if practice is continued, cotton should be used in the ears.

The striking of children about the head, and the pulling of the ears, are, of course, bad for many reasons; but it is especially necessary to avoid them to prevent ear-thickenings and ruptures. Many a patient with serious ear-trouble attributes it entirely to this cause.

Habitual late hours have a bad effect upon the ears of some. Of course, if there is the slightest evidence of the existence of this cause, the sleeping hours should be lengthened.

Of the injury which tobacco occasions, much can be said. There are those who are very susceptible to tobacco, especially when it is smoked; on these the absorbed nicotine seems to exert its influence primarily on the auditory nerve and ear-structures. This effect is much more frequent and more marked upon children who are not fully developed. Its effect upon the ears of growing boys is often very noticeable; in children of six or ten years of age, it almost invariably impairs the hearing. Many cases of pronounced deafness have originated from this habit, the mischief being done while the patient was unconscious as to the cause. Children under eighteen years of age should never be allowed to smoke tobacco. In proportion as they grow older does the probability of resulting ear-trouble diminish, but, should the slightest impairment of hearing come on, the tobacco habit should be immediately stopped, as in such cases its effect is always deleterious.

Opium-eaters and smokers often suffer with ear-affections, which are preventable only by the discontinuance of the habit on the slightest evidence of ear-difficulty. Cigarettes, not infrequently containing opium as well as tobacco, are often very injurious. Quinine deafness is to be guarded against by the discontinuance of the drug whenever this is necessary. The excessive use of coffee is to be discouraged. Whenever it seems injurious to the ears, it should no longer be used.

Some occupations are liable to bring with them ear-troubles. It is hard for boiler-makers, workers in match and lead-paint factories, and in mills, as well as those employed where monotonous noises are fairly constant, or where sudden excessively loud noises are occurring, to escape ear-troubles. Much can be here accomplished in the way of prevention by the use of cotton within the meatus, by ear-inflation, and by thorough cleanliness. An easy and effective method of prevention is the regular systematic examination of the ear, for instance, every six or twelve months, followed by treatment, if necessary.

Should at any time any symptoms occur, the ears should be immediately examined and treated.

It will be realized that prevention consists not only in avoiding the causes of ear-disease whenever possible, and, when this cannot be done, in the taking of precautions to forestall the possible effect; but also in immediate treatment, whenever the ear is threatened, with the view of aborting the ear-trouble. When this cannot be accomplished, the effort should be so to limit the disease that the ear suffers the least possible impairment.

The importance of this course, and its great value, must be impressed upon the laity, who for too long a time have believed that "ears will get well of themselves"; that "the hearing will get worse if treated"; that it is "better to allow the discharge in children to continue"; that "it will disappear as the child grows"; or that, anyway, the trouble is slight, as it is "only an ear." Teach them that precautions should always be taken, but tell them particularly that, whenever any ear-trouble is threatening or has appeared, to have it treated immediately, and treated until it is well. Tell them that ear-disease is usually, in its commencement, easily cured; and, if advanced, that it can be greatly alleviated; but, if let alone—as is so often advised by friends, as well as sometimes by the medical adviser—that the result is sure and distressing. If we do this, we will have done our duty, and accomplished at least a little toward alleviating the pain and inconvenience, of which there is always sufficient with us.

Northwest corner Sixth and Green Sts., Phila.

SOME NEW INSTRUMENTS.

BY A. ADY, M.D.,
MUSCATINE, IOWA.

Uterine Constrictor.

In the operation of trachelorrhaphy as a means of controlling hemorrhage from the cervix, the firm of Tiemann & Co., New York, made for me a simple and inexpensive instrument which answers the purpose admirably, and is not in the way of the operator.

It consists of a canula like a catheter, bent to fit the anterior part of the vagina and hook around the pubes. At the outer end is a screw like that in a light and small écraseur. The loop that goes around the cervix, as seen in the cut, is of twine or fine copper wire (which is the easiest to adjust). To use the instrument, grasp the os with tenaculum, pass the loop over it and around the cervix. One end of the cord or wire being fastened to the peg, pull the other through and give it a few turns around the same; the loop can then be tightened by a few turns of the screw.

The instrument is very light, needs no assistant to hold it, and is easily cleansed.

Elastic Stem Pessary.

In treating uterine flexures or curvatures unconnected with great stenosis, I have had trouble with a rigid stem pessary, which causes irritation of the part. Conceiving the idea that elastic pressure would be the proper mode of treating those as well as flexures of other parts of the body, I applied to Messrs. Tiemann & Co., of New York, who constructed the instrument represented in the wood-cut below. It is made of soft red rubber, of the same shape as an ordinary simple stem pessary, with a flange at the lower end fitting smoothly over the cervix, but perforated so as to allow free discharge of secretions. The stem is hollow, so as to allow the introduction of an elastic stylet of any desired strength the operator may wish, but great force is not necessary. The stylets can be made by any person, whittled out of whalebone or hard rubber, left large enough at the outer end to tightly fill the stem, exclude the moisture, and retain it in place.

In ordinary cases, the stem can be introduced with the stylet in position; but, when the parts are intolerant, the rubber alone can be worn until a tolerance is established, after

which the spring is easily slipped in without the least danger of lacerating or irritating the over-sensitive endometrium. Under elastic pressure applied in this way, curvatures soon disappear. Other pessaries for retaining the uterus in position can be worn at the same time without interfering with this one. When the uterus is in normal position, the vaginal walls exert pressure enough to keep the stem in position. When they do not, pledgets of antiseptic wool or cotton should be used. These stems should be made of two lengths and sizes, 2¼ and 2½ inches long and Nos. 6 and 10 in size. The size and length of the stylet can be made to make quite a difference in their size and length.

The stylet in the above cut is pictured too long: it should be no longer than the cavity in the stem.

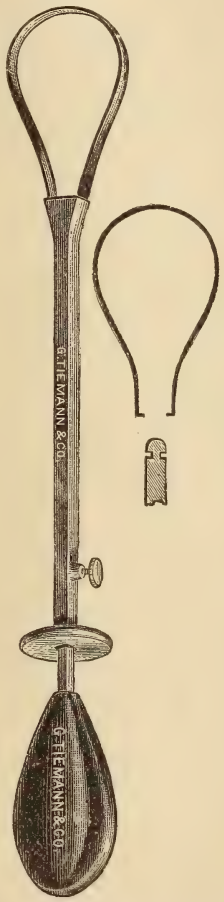
Uterine Tourniquet and Expanding Curette.

This instrument was originally invented and used as an expanding curette and roughly made of a piece of watch-spring and a piece of catheter. This was sent to Messrs. Tiemann & Co. to have a more perfect one manufactured. I thought from their model that it could be used as an improvement on

Emmet's uterine tourniquet, and such proves to be the case.

It is light, small, and can be taken apart for cleaning by turning one set-screw.

We should have several different lengths of watch-spring loops; for the tourniquet, the latter is better made light, but, when used as a curette, it should be of the strongest. In doing Emmet's operation, place the loop around the cervix, tighten it by pushing on the flange to any desired tension, and fasten it by the set-screw; it will not slip off or come loose during the operation. It is very easily controlled.



When it is desirable to use it as a curette, put in a heavier and shorter loop, and draw it back into the canula, when it is easily introduced into the uterine cavity where it can be expanded, by pulling on the flange with the thumb, to any desired extent. The piece of watch-spring adapts itself to the cavity, and, when rotated, will detach anything that may be attached in shape of a secundine, without danger of lacerating the uterine walls.

THE GERM THEORY OF TYPHOID FEVER AND THE THERAPEUTIC INDICATIONS IT SUGGESTS.[1]

BY J. A. ELLEGOOD, M. D.,
LAUREL, DEL.

It is now commonly believed that typhoid fever has for its immediate cause the ingestion and development within the human body of a living germ, and, while proofs to this end are not as yet conclusive, we are in possession of sufficient knowledge to establish this opinion with considerable degree of probability. The presence of special microbes in typhoid fever was first observed by Recklinghausen in 1871; but, for an exact description of this minute organism, we are indebted to the recent researches of Eberth and Klebs. This organism, which they found in a large percentage of the cases examined, and to which they gave the name *bacillus typhosus*, belongs to that group of bacteria called Schizomycetes.

This group was for a long time classed with the vegetable fungi, but recent researches into their organization and reproduction show that they resemble a group of inferior algæ termed *Phycochromyaceæ*, but that they differ from the other members of this group in being devoid of chlorophyl. No sharp line, however, divides the fungi from the algæ, and many families of each are really correlated, inasmuch as they agree in the characters of reproduction and alternation.

Zopf asserts that the same species of alga may accommodate itself to two very different modes of existence. When these algæ are found in water or on damp soil, they exist in the form of plants, and live and multiply by means of chlorophylaceous protoplasm; but, when deprived of moisture, a contraction of the protoplasm in the interior of the cells takes place, forming spores; the cell-walls rupture, and the spores thus set free become air-germs, and are wafted about by the slightest breeze. When these germs encounter a favorable medium, they develop, first, in the form of micrococci, then of bacteria, bacillus, or that of whatever species to which the spore in question belongs. The bacillus typhosus appears in the form of long and short rods, slightly constricted in the middle, and with rounded extremities. They are formed of a thin membrane of colorless cellulose, filled with

[1] Read before the Delaware State Medical Society, Georgetown, Del., June 12, 1888.

a colorless protoplasm. They are about 0.0002 mm. thick, and form filaments up to 0.05 mm. long. They contain vacuoles or spores, and stain easily with methyl-violet. Multiplication is effected by fission, each half becoming of the size and shape of the parent cell and soon splitting again.

The long ones are found only in the intestinal glands, the short ones in the mesenteric glands, spleen, liver, often in the red corpuscles of the blood, and sometimes in the kidneys and urine of typhoid fever patients. They are numerous in the intestines when ulceration of the solitary and agminated glands begins, but become fewer and are succeeded by other microbes as the disease approaches its end.

The bacillus in question is, however, the only one found in the blood and internal organs during the fever, and has never been found associated with any other disease than typhoid fever.

The fact that the bacillus has not been found in all of the cases examined is no proof that the disease is a non-bacterial one; for, aside from the difficulty of the demonstration of bacteria, it should be remembered that post-mortem material is not well suited for this purpose, since the patients examined generally live to an advanced stage of the disease, and, in many cases of bacterial affections, all traces of bacteria have disappeared by the time the tissue-changes occasioned by the invasion are complete. Gaffky, a pupil of Koch, has succeeded in the artificial culture of the microbe taken from the spleen of patients who had died of typhoid fever, and found that it developed actively on gelatine and potatoes. At a meeting of the Medical Society of Lyons, July 27, 1887, M. Rodet presented some slides made from the sediment of drinking-water in places recently ravaged by typhoid fever, and at the same time some mounts prepared from a mesenteric ganglion of one of the deceased typhoid fever patients. In all of them, the typhoid bacillus was present in great quantity, and the bacilli in the sedimentary mounts were identical with those in the mounts of the mesenteric ganglion. Brautelecht found the bacillus typhosus in suspected drinking-water and in the urine of typhoid fever patients. Cultures made from these and injected into rabbits produced fever. Tizzoni also isolated the bacillus in question from drinking-water during a typhoid fever epidemic; injected into rabbits, it produced symptoms in many respects resembling typhoid fever, and, in the tissues, the same character of bacillus as that observed in man was found. So far as the characteristic intestinal lesions are concerned, the attempts to reproduce typhoid fever in animals by inoculation have been unsuccessful.

Before a disease can be considered due to the presence of a specific microbe, the four following conditions must be fulfilled (Koch): 1. "The microbe in question must have been found either in the blood or tissues of the man or animal which has died of the disease."

2. "The microbe taken from this medium and artificially cultivated out of the animal's body must be transferred from culture to culture for several successive generations, taking the precautions necessary to prevent the introduction of any other microbe into the culture, so as to obtain the specific microbe pure from every kind of matter proceeding from the body of the animal from which it originally came."

3. "The microbe thus purified by successive cultures and reintroduced into the body of a healthy animal capable of taking the disease ought to reproduce the disease in question in that animal, with the characteristic symptoms and lesions."

4. "Finally, it must be ascertained that the microbe in question has multiplied in the system of the animal thus inoculated, and that it exists in greater number than in the inoculating liquid."

That all these conditions have not been fulfilled, as regards the bacillus of typhoid fever, is probably due to the fact that the experiments have not been performed upon animals capable of taking the disease, or, if capable, the germ has not been introduced into the system through the alimentary canal. It is well known that certain bacteria produce very different effects, not only according to the animal into whose body they are introduced, but also according to the part of the body into which they are injected. Since circumstances indicate that the cause of typhoid fever is introduced into the body through the medium of ingesta received into the alimentary canal, it might reasonably be supposed that the intestinal glands represent the points of invasion and local settlements of the germ, and afford the conditions most favorable to its existence and reproduction. Were the intestinal lesions of trophic origin, they would as invariably be reproduced by inoculation as they are present in spontaneous cases. As further evidence that the poison gains entrance into

the system through these glands and here produces the primary irritation, we have only to refer to the fact that the mesenteric glands most involved are always those most directly related to the ulcerated areas.

The action of the germ as a pathogenic microbe is virtually that of a specific ferment, and the phenomena are of the same order as those which characterize the regular accomplishments of animal life. Like all other forms of life, whether of animal or of vegetable nature, it breathes by absorbing oxygen. It is not necessary, however, for its existence, that the oxygen exist in the form of air, and on this account it is called an anærobic microbe. It is capable of withdrawing from oxygenated substances the oxygen necessary for its respiration, and the decomposition which it excites in organic compounds is in part a consequence of the disturbance of equilibrium resulting from this respiration. Beside oxygen, it requires to be supplied with certain definite nutritive substances, and the mineral salts, alkaline and alkaline-earthy phosphates, nitrogenous substances, and carbohydrates contain elements necessary to its normal development. These substances are decomposed by it under proper adjustment of temperature and of moisture, and what is suitable to itself is appropriated out of these various compounds. The nutritive activities of the bacillus as a human parasite involve disintegration and appropriation of some of the elements of the fluids upon which the tissues depend in the expression of their cell life; and degeneration and necrosis of the fixed cells may be brought about by local settlements of the germ, and in consequence of a disturbance in various ways of the circulation, or because of a special mechanical action exercised upon the ultimate particles of compound matter of which the tissue cells are composed.

The special changes it calls forth are determined by the constitution of the soil upon which it feeds, and by the special nature of its wants. We do not know the nature of the influence which it brings to bear upon the nutrient medium, nor can we formulate the changes it excites. "No one doubts that in organic living cells, whether they be isolated or form an integral part of a more complicated organism, there resides a special force, capable of producing chemical reactions under conditions quite different from those which we employ in our laboratories, and to produce results of the same class.

"This force, which we imagine to be as material as heat, reveals to us its activity by decompositions effected on complex molecules." We may believe that bacteria do not communicate to the organic compounds contained in the juices the same kind of chemical motion as do the tissue cells, and therefore do not give rise to the same chemical changes as the latter.

Since the bacillus is never found in great quantity in the blood, the energy stolen and expended in the performance of its physiological processes and the mechanical traumatism which it effects, will not account for the severity of the ataxia of typhoid fever. A study of the nature and actions of the germ leads us to conclude that the disturbance which it causes represents more of its chemical than of its physical effect, and that this effect is manifested through the production of poisonous substances which have more to do with the genesis of the symptoms than has the mere withdrawal of nutriment. Only a limited portion of the medium from which the microbe withdraws its nourishment is utilized by it in the production of force, and the greater portion of the molecule broken up, now dissociated, seeks other relations and forms new products foreign to the animal organism. Beside these, it probably gives rise to other products of excretive or secretive origin. These substances are but slightly soluble, not easily eliminated, and of toxic character. Those products which result from the disintegration of albuminoid substances are regarded as especially noxious, and their actions are analogous to those of some of the poisonous vegetable alkaloids. From artificial cultures of the bacillus taken from typhoid fever patients, a crystallizable alkaloidal substance has been obtained, whose physiological actions correspond in many respects to the clinical features of the disease. Whether this substance is of a secretory character or a by-product of decomposition has not been determined. The alkaloidal substances formed during the decomposition of albuminoid substances are called ptomaines, from $\pi\tau\tilde{\omega}\mu\alpha$, a carcass, because they were first obtained from corpses and putrescent organic matter. The relation of microbes and ptomaines can be easily demonstrated. By means of a Chamberland filter they can be separated, and, if the microbe be transferred to the infusions of successive cultures so as to purify it from every foreign element, it continues to produce its characteristic ptomaine, which is manufactured completely at the expense of the culture liquid. No ptomaine, however, is developed without its special microbe.

Brieger proposed, for the poisonous ptomaines, the affix toxine, and, adopting his nomenclature, we call the ptomaine of typhoid fever *typhotoxine*.

"From cultures of the typhoid bacillus he obtained the basic typhotoxine, $C_7H_{17}NO_2$, which produced in small animals lethargic conditions with liquid dejecta." The disposal of ptomaines, as well as other products of tissue metamorphosis which accumulate in the system during the fever and which are not eliminated by the respiratory organs, kidneys, and skin, is effected largely by oxidative changes, which give rise to soluble and easily eliminated waste. If oxygen be supplied in abundance to a fermenting albuminous liquid, the primary products of decomposition at once undergo further change. The oxygen oxidizes them as they are formed.

The increase of temperature in typhoid fever involves an increase of organic disintegration without a corresponding increase of constructive metamorphosis, and is due: 1. To chemical changes excited by the parasite itself—phenomena, for the most part, of hydration and reduction. 2. To diminished elimination of caloric—owing to cutaneous capillary contraction and diminished excretion of water. 3. To excess of reactions which normally occur in the body during the acts of nutrition, which excess is the result of the action on the nervous system of the products of bacterial decomposition. It is probable that these products excite nervous impulses which call forth increased metabolism, and that this does not represent a true exaggeration of the physiological process of calorification, but that omissions or changes occur in the rela tive proportions of that series of actions by which, in health, the two constant movements of composition and decomposition are accomplished. In consequence of this, there is in the system an accumulation of products of imperfect disintegration which are still capable of contributing to organic synthesis and the formation of new cells, and which have not reached the limit of splitting up at which they naturally become excrementitious.

It appears that the accumulation of these products in the circulation, which are sometimes called leucomaines, gives rise to separate and additional disturbance.

Until a comparatively recent time, the increase of temperature in typhoid fever was supposed to be secondary to increase of organic oxidation. It is now known that oxidation is not the exclusive source of animal heat and febrile pyrexia, but that in typhoid fever, in comparison with the other reactions which take part in the production of the pyrexia, oxidative changes undergo a remarkable diminution—a diminution much greater than that for which the reducing agency of the bacillus will account.

It is also known that the chemical reactions which accompany the transformation of proteids and their immediate derivatives are, for the most part, phenomena of hydration, and "that disassimilation is accomplished by the successive acts of which the first are hydrations and chemical combinations, which give rise to products which are only secondarily overcome by oxidation, and that animal heat results from the *ensemble* of all these reactions." To determine the relative diminution of the oxidation of the nitrogenous elements in fever, the quantity of urea eliminated is compared with the total quantity of urinary solids, and these proportions with those which exist in health.

We know that typhoid fever is a self-limited disease, but what determines its duration we do not know positively.

Although we cannot deny that susceptibility to the disease is increased through the agency of influences which tend to lower the general condition of vitality, the history of epidemics leads us to believe that the conditions fit for the existence and growth of the bacillus are ever present in the system, and that all that is necessary for the development of the disease is its introduction into that part of the body which it especially invades. The relation which age bears to typhoid fever is in proportion to development or condition of the intestinal glands, which undergo ulceration during the disease. It has been stated that the glands of Peyer are most fully developed at puberty and begin to disappear after adult life, and that traces only of their existence are apparent after forty-five. Post-mortem examination of victims of typhoid reveals less extensive abdominal lesions in young children and old persons, and there is little doubt but that immunity from repeated attacks is great, and the severity of such cases less, in proportion to the previous destruction of these glands.

The therapeutic indications based upon the germ theory are: 1. To destroy the germ; 2. To combat its effects.

Although it may seem that the problem of destroying the germ may not be so difficult, provided the opportunity of treatment is early offered, we are, nevertheless, as yet,

in view of our imperfect knowledge, unable to destroy directly the morbific organism which gives rise to the disease, when once it has gained access into the body.

Since the ataxic symptoms of typhoid fever are secondary and usually proportionate to the elevation of temperature, the primary aim in combating the effects of the germ is the reduction of fever and the restraining and regulation of organic disintegration, to the exaggeration and modification of which the pyrexia is mostly due.

Reduction of temperature is accomplished—1. By the external application of cold; 2. By the internal administration of antipyretics. The application of cold affects not only the abstraction of heat from the body, but promotes the regulation of organic disintegration, and tends to restore the normal process of heat-production by increasing the absorption of oxygen. Frédéricq has shown that "cold, when acting upon the cutaneous surface of man, augments manifestly the ratio of oxygen absorption and carbon-dioxide production"; and Quinquaud, who has carefully studied the action of cold and heat on the chemical phenomena of nutrition, has also arrived at the conclusion that cold baths augment the absorption of oxygen and the activity of interstitial combustions.

Cold baths probably promote absorption of oxygen by the reflex stimulation which they exert on the nervous system, and, as previously stated, oxidation diminishes the formation of ptomaines and the products of defective disintegration, and assists in the elimination of those already formed. It is obvious, then, that much good can be accomplished by the use of agents which set free or favor the absorption of oxygen. Among the agents which fulfill this indication are alcohol, the salts of organic acids, the free ingestion of liquids, and the inhalation or rectal administration of pure oxygen.

Antipyrine and antifebrine, the internal antipyretics most extensively employed, neither affect the special cause of the fever nor assist in the removal of the incompletely-oxidized organic residue. They diminish nitrogenous disintegration probably by depressing the power of the cells of the heat-centre to respond to stimuli, or by lessening the power of the afferent nerves, or those portions of the cord which transmit the impulse from that centre. The next indication is to repair the destruction and degeneration of tissue and the promotion of nutrition by judicious alimentation.

In concluding this paper, the writer desires, for the promotion of science, and thereby the good of humanity, to make the following suggestions:

1. That a national or international experimental commission be appointed to make investigations, with a view of determining the cause and best method of treating typhoid fever.

2. That, in addition to the lower animals, human beings be made the subjects of experiment.

3. That, in order to obtain human subjects for experiment, criminals sentenced to capital punishment or long terms of imprisonment may have their sentences commuted, and that, instead of suffering the usual penalty of their crimes, may become the subjects, for a specified time, of experiment.

4. That no one be chosen who is not a voluntary offering, and that no one be subjected to tortures or absolutely fatal experiments.

PERISCOPE.

Diuretic Action of Strophanthus.

At the meeting of the Biological Society of Paris, June 9, 1888, M. Lemoine, of Lille, stated that polyuria is the most constant of all the effects produced by strophanthus. He has always determined this by giving the tincture of strophanthus to healthy persons. Five or six drops are sufficient nearly to double the quantity of urine in forty-eight hours. He has nearly always secured diuresis in patients with heart-disease, unless they were in a condition of complete asystole, when strophanthus is at times, though rarely, incapable of bringing about diuresis. It fails especially when there is extensive pulmonary œdema and great embarrassment of the pulmonary circulation.

It is a singular fact, he says, that the diuretic effects of strophanthus persist for a very long time after it has ceased to be administered. The urine decreases to the normal amount only by insensible degrees. Fifteen days after the drug has been stopped, the patients still pass two quarts of urine, although when they were taking strophanthus the daily quantity was three quarts, and before treatment only about thirteen ounces.

M. Lemoine does not think that strophanthine gives as satisfactory results. In three patients, tincture of strophanthus has occasioned a profuse serous diarrhœa, which was controlled only by stopping the drug.—*Bulletin Médical*, June 13, 1888.

Cancer of the Larynx.

At the meeting of the Société Française d'Otologie et de Laryngologie, April 26, Dr. J. Charazac, of Toulouse, related a case of cancer of the larynx, and made some remarks on the treatment of that disease. The patient, a healthy man, aged sixty, had for years been subject to frequent attacks of hoarseness, and he had besides been an immoderate smoker. He had never had syphilis, but it may be worth mentioning that his wife had died some years before of cancer of the breast. For eighteen months before he came under the notice of Dr. Charazac, he had suffered from persistent aphonia.

On October 1, 1887, the epiglottis and the left side of the larynx showed the ordinary signs of chronic laryngitis; on the right side there was a deep ulcer with grayish base occupying the centre of a swelling which involved the ventricular band and reduced the glottis to half its natural size. Dr. Charazac diagnosed the affection to be malignant, and proposed laryngectomy, which was declined. On February 19, tracheotomy became necessary, and the disease has since made steady progress. The most troublesome symptom at the date of the report was the passage of food into the larynx; this was found to be due to the fact that the tumor, as it increased in size, pushed up the epiglottis so as to interfere with its action in swallowing. In discussing the treatment, Dr. Charazac compared the results of simple tracheotomy with those of extirpation of the larynx for cancer. Statistics showed that the former increased the average duration of life by six or eight months, while after laryngectomy two-thirds of the patients died either from the immediate effects of the operation or from rapid recurrence of the disease. This discouraging result is, however, in Dr. Charazac's opinion, due rather to the want of a proper selection of cases than to any inherent fatality in the operation. He thinks that, as a rule, it should not be performed in patients over seventy, and he looks upon it as absolutely contra-indicated in all cases in which the glands are affected or the general health impaired. It should never be done unless the disease is strictly limited to the interior of the larynx, but in suitable cases early operation is imperative. If these rules are adhered to, Dr. Charazac believes that laryngectomy will prove much more successful in the future than it has been up to the present time.—*British Med. Journal*, June 30, 1888.

Rare Case of Eclampsia.

At the meeting of the Obstetrical and Gynecological Society of Paris, June 14, 1888, M. Charpentier said that on May 17 he was called to see a young primipara six and one-half months pregnant, who had been taken on the preceding night with eclampsia. He was informed that toward the end of the fourth month the patient had suffered with œdema of the lower limbs and that the family physician had discovered a considerable quantity of albumin in the urine, and had advised a milk diet. This advice was not followed.

On the night of May 16–17, she had a violent attack of eclampsia. The following day, when M. Charpentier saw her, there was enormous œdema, marked dulness, and embarrassment of speech. Heat showed abundance of albumin to be present in the urine. The temperature was normal; the pulse 80. She was ordered milk diet, and given chloral. The next day, the albumin had considerably diminished, but there appeared great pain at the pit of the stomach. The fœtal heart-sounds were absent. Chloral and morphia were given. During the night of May 19–20, there were three convulsions at intervals of half an hour. On the morning of 20th, acute epigastric pain and headache were present. On the 21st, the symptoms improved a little, but, by the 22d, there was trouble with vision. The next day, improvement occurred and persisted. On June 2, the patient was delivered of a fœtus, which was dead and macerated.

The interesting points about the case are that the woman took no precautions to avoid the serious danger to which she was exposed, the small number of convulsions, the death of the fœtus from the first convulsion, normal temperature throughout, the appearance, after the attack, of symptoms usually regarded as prodromic—*Bulletin Médical*, July 8, 1888.

Entrance of Air into a Vein.

At the meeting of the Surgical Society of Paris, July 4, 1888, M. Reynier stated that very recently, while removing a tumor from the carotid region of a young man, he heard a gurgling sound, such as air produces as it enters a vein. For two days, no accident occurred; but, on the third day, the bruit was renewed, and was followed by sudden death. At the autopsy, M. Reynier found a hole in the jugular vein, and a considerable quantity of air in the vein.—*Bulletin Médical*, July 8, 1888.

Atypical Varieties of Lupus Vulgaris.

At the meeting of the Academy of Sciences of Paris, July 16, 1888 (*Gazette Hebdomadaire*, July 27, 1888), M. Henri Leloir read a note upon the atypical varieties of lupus vulgaris, and expressed the opinion that these, as well as the classic form of the disease, should be regarded as attenuated tuberculosis of the skin. He recognizes three atypical varieties—the colloid, the mucoid or myxomatous, and the sclerous, which are so named by reason of the characters which they present. He uses the word "attenuated" tuberculosis because (1) these forms contain few bacilli; (2) infection of an animal occurs much more slowly than if true tubercle is employed; (3) unless very large particles of lupus are inoculated, the inoculation may be negative.

He thinks it is important to recognize these atypical varieties of lupus in order to avoid errors in diagnosis.

Rapid Method of Using Fehling's Test for Sugar.

In a communication to the *New York Medical Journal*, July 7, 1888, Dr. Walter Mendelson says that everyone who has critically examined many specimens with Fehling's solution will have noticed two striking facts. The first of these is that some urines from which sugar can by various tests be positively excluded will decolorize the solution, and even give it an orange or opalescent-green tint. The second is that urines known to contain sugar fail to produce a characteristic precipitate with Fehling's test, giving instead appearances identical with those just described, or filling the test-tube with a precipitate usually of a yellowish-green color, which never turns red and never satisfactorily settles to the bottom, and which is, moreover, so fine as to pass through most filters. The reason for these disturbing variations from the classical action of the test, as described in the books, is to be found in the fact that urine contains normally two classes of bodies, one of which has the power of reducing copper oxide, and the other of redissolving such oxide when from any cause it has been reduced. We have then, he says, two substances of antithetical action, the final result of their presence depending upon which preponderates in quantity. The less sugar the specimen contains, the more disturbing these variations become, and it may happen that as much as one-half of one per cent. of sugar is present without a characteristic precipitate being formed. Concentrated high-colored urines are, as a rule, more apt to show these peculiarities than dilute pale urines. Two kinds of error are consequently likely: One that traces of sugar may be overlooked, the other that traces may be reported in urines containing none.

To avoid these difficulties, he advises the following procedures: First, use a flask capable of containing about 250 c. c. (8½ oz.), and, after adding the usual 10 c. c. (160 minims) of Fehling's solution, fill half full of water, or until the solution is of a very pale blue. The reaction takes place much better and can be more closely observed than when the test solution is used in concentrated form. Second, the urine should be well diluted. Make a preliminary qualitative test to judge approximately of the quantity of glucose present and dilute accordingly. One in ten is a convenient strength. This, together with the thinning of the Fehling's solution, will insure proper dilution of the normal reducing and dissolving substances of the urine, and minimize their disturbing action. The temptation to use the urine but slightly diluted or of full strength when the amount of sugar is small, so as to shorten the time necessary in using the burette, is very great, but will always be regretted if yielded to, for it generally ends in compelling one to undertake the whole analysis afresh after wasting considerable time.

Put the diluted Fehling's solution on to boil while preparing the dilution of urine and filling the burette. Then, when all is ready, in starting the process, allow only a small quantity—from one-half to one c. c. (8-15 minims)—to flow from the burette before boiling again, removing the flame and allowing the ebullition to cease each time before adding more. *Boil hard* each time, as this causes the particles of oxide to cohere and fall to the bottom more quickly than otherwise.

Even under the most favorable circumstances—that is, when a red precipitate appears at once and falls quickly to the bottom as the reaction nears completion—a considerable time must always elapse before the supernatant fluid is sufficiently clear to allow the analyst to determine whether all the blue color has been discharged or not, especially as the fine particles of red oxide, when in suspension, give to an otherwise colorless fluid a violet shimmer. This settling may be hastened by adding a dash of cold water to the

contents of the flask; but Munk has devised a method which is probably the greatest improvement in the use of Fehling's solution since the test was first proposed, and which Dr. Mendelson desires to popularize. This improvement consists in adding a small quantity of a solution of calcium chloride to the mixture in the flask. (Munk recommends three to five drops of a 15 per cent. solution, but in practice Dr. Mendelson simply makes a pretty strong solution, and uses as much as seems needed.) A voluminous, white, curdy precipitate is formed, consisting in part of calcium hydroxide and in part of calcium tartrate, the latter being less soluble in hot than in cold solutions. This precipitate, from its curdy gelatinous nature, carries down with it the impalpably fine powder of the copper oxide, and quickly leaves a clear supernatant fluid in which the most delicate shade of blue is discernible, if present.

In practice, Dr. Mendelson has found the following the best mode of procedure: If the oxide comes down red in the beginning, he continues adding from the burette until the rapid falling of the precipitate to the bottom of the flask warns that the reaction is nearly complete. He then adds about ten drops—or enough to give a pretty large quantity of precipitate—of the calcium-chloride solution. When the precipitate of copper is yellowish-green and shows no sign of turning red, he adds the calcium-chloride solution as soon as he has satisfied himself of the latter fact. Great care, he says, must be used to boil slowly at first, allowing the flame of the burner to play gently, with frequent removals, about the bottom of the flask until the whole mass gradually boils. If this is not done, owing to the character of the precipitate, explosive boiling may occur, and the whole contents of the flask be suddenly landed on the ceiling.

When boiling is once under way, there is no more danger of such an accident occurring, and ebullition should be maintained for some minutes before the precipitate is allowed to settle. Should it be found, after the calcium tartrate with the copper oxide has settled to the bottom, that considerable copper still remains in solution to be precipitated, it will generally be necessary to add from time to time, as the urine is run out of the burette, a few drops more of the calcium-chloride solution, as the freshly precipitated calcium tartrate has greater clarifying powers than that which has already been used. Should the amount of precipitate become finally very large, more water should be added to the flask. By the use of this method, he says, a sugar determination may be made in twenty minutes, and several can be done together in even less time each; whereas, under the common method, half an hour would be very short and very exceptional, and an hour or more—depending on the nature of the specimen—nothing unusual.

In conclusion, he says: "Two years' constant use, embracing specimens of all varieties of contrariness, warrants me in heartily recommending Munk's method to all who have many, or indeed any, quantitative determinations to make, and to whom time is valuable."

Caffeine in Heart Disease.

At the meeting of the Therapeutical Society of Paris, July 11, 1888, M. Huchard stated that some time ago he had had the care of a woman 70 years old, who had heart disease of arterial origin, accompanied with complications. Digitalis for a while did good, but eventually failed, so that M. Huchard almost despaired of the patient's recovery. He then tried caffeine hypodermically, according to the following formula:

Benzoate of soda	gr. xlv
Caffeine	gr. xxx
Distilled water	℥xc

M. Sig. For hypodermic injection.

He gave four, five, and six of these injections a day, and under their influence the pulsations of the heart became more energetic, the patient became stronger, and the excretion of urine, which had been nine and one-half ounces, increased to thirty-eight and forty ounces. He believes that caffeine exercises its action especially upon the nervous system.—*Bulletin Médical*, July 22, 1888.

Exstrophy of the Bladder.

At the meeting of the Academy of Medicine of Paris, July 24, 1888, M. Léon Le Fort presented a boy upon whom he had successfully operated for exstrophy of the bladder, a congenital malformation consisting in the absence of the anterior wall of the abdomen at the level of the bladder. He was able completely to cover in the bladder and to make a channel for draining the urine, so that it no longer flowed upon the groin and thighs, but into a rubber receptacle which could be easily hidden under the clothing.—*Gazette Hebdomadaire*, July 27, 1888.

Abscess Outside the Tonsil in an Infant.

Dr. W. Pasteur, physician to the Northeastern Hospital for Children, reports a case of this kind in the *Lancet*, July 14, 1888. He was unable to discover the exciting cause of the suppuration. The region involved was the cellular tissue outside the right tonsil and the tonsil itself. The posterior wall of the pharynx was quite free, and there were no signs of spinal caries. There were no enlarged glands in the neck.

The patient, three months old, was brought to the out-patient department of the Northeastern Hospital for Children last February, with the following history: The infant had been breast-fed, was always fairly healthy, and had been well cared for. Ten days previously, the mother noticed that the child had some difficulty in swallowing, and breathed badly when he was at the breast A doctor was called in, who ordered hot fomentations to the neck. The child became rapidly worse. After three days, a swelling was noticed in the right side of the neck. A week later, the child's condition was so alarming that the mother brought him to the hospital. The patient was a rather wasted, pallid infant, with labored catching breathing, not unlike that in a bad case of catarrhal laryngismus. Swallowing was practically impossible. There was a diffuse deeply fluctuating swelling in the right side of the neck at the anterior border of the sterno-mastoid. The skin over it was moderately tense, but was not reddened. On looking into the mouth, the passage of the fauces was seen to be almost entirely occluded by a large swelling in the position of the right tonsil. By passing the little finger carefully behind this, it was ascertained that the pharynx was perfectly free, and that a distinct fluctuation-wave was also communicable from the tonsil to the tumor in the neck. At Dr. Pasteur's request, Mr. Blake, the house surgeon, made a short incision into the most dependent part of the tumor in the neck, and evacuated three ounces of inodorus green pus. The swelling at the back of the mouth immediately disappeared, and all the distressing symptoms were at once relieved. A probe passed through the wound impinged against the finger on the tonsil with only mucous membrane intervening. The wound healed completely in ten days. The child was kept under observation. He remained absolutely free from all throat-trouble until June 19, when another abscess of the same size formed in exactly the same situation in the course of a few days, giving rise to an identical train of symptoms. The same operation again gave instant relief. On this second occasion, the abscess-cavity was explored with the finger, and its relation to the tonsil clearly established. In the neck, the cavity lay in front of the great vessels.

Transmission of Tuberculosis by Means of Flies.

In the REPORTER, October 15, 1887, p. 517, we published a brief note on a communication to the Academy of Medicine of Paris, by MM. Spillmann and Haushalter, in which they showed that it was possible for flies to carry with them the contagion of tuberculosis. A new and highly interesting contribution on this subject has been recently furnished, says the *Wiener med. Presse*, July 29, 1888, by Dr. E. H. Hoffmann, of Dresden, whose communication is contained in the *Deutsche Medizinal-Zeitung*, No. 57. It seems that Dr. Hoffmann found some flies in a house in which a patient had died with advanced tuberculosis, and whose sputum had contained great quantities of tubercle bacilli. These he took home and subjected to examination. Tubercle bacilli were found in their intestines, at first in larger and subsequently in smaller quantities. Their excretions, which covered the walls of the house in the form of numerous specks, also contained tubercle bacilli. Dr. Hoffmann prepared the specimens by carefully taking a speck of fly excrement from the wall with a platinum needle, and rubbing it with water upon a cover-glass. In no preparation obtained in this way did he fail to find the bacilli. As often as he had before examined flies in his house, he never had been able to find bacilli in either their intestines or their excrement. On the other hand, he fed some flies, which were apparently healthy, upon tuberculous sputum, and found that, in a few days, a large number of the flies died, so that the chandeliers were covered with dead flies.

To determine the vitality of the bacilli transmitted by the flies, he inoculated them into the anterior chamber of the eyes of guinea-pigs. Of five experiments, four were without result. In one, however, the success was complete: at the autopsy, a large number of fresh small tubercle nodules were found in the lungs, liver, and spleen, while the bronchial glands were swollen. The question of the vitality of the bacilli transmitted by flies must, therefore, be answered in the affirmative.

Slow Facial Palsy in Fractures of the Petrosa.

A. Demoulin, in a series of papers on this subject (*Gazette Médicale*, July 7, 14, and 21, 1888), finds that facial palsy in fractures of the petrous portion of the temporal bone may be slow in making its appearance. In such cases, it should be referred, he says, to the compression of the nerve by swelling of the periosteum which lines the aqueduct of Fallopius, at the time when the work of repair is going on. Increase in the volume of the nerve itself, occasioned by congestion, should also be taken into account. This slow facial palsy is always slight, and its prognosis is always favorable. In case the diagnosis of fracture of the petrosa is held in suspense, the appearance of slow facial palsy makes it possible to affirm the existence of fracture.

Etiology of Vulvo-vaginitis in Children.

At the meeting of the Second Congress of the German Gynecological Society, at Halle, May 26, 1888, Dr. Pott, of Halle, stated that among 18,074 children treated by him from April, 1876, to April, 1888, there were 8,481 girls. Of these, 86 suffered with vulvo-vaginitis. The numbers corresponding with the periods of life were as follows: Up to 5 years of age, 56; from 5 to 10, 23; from 10 to 15, 7. The origin of the affection, he said, was partly referable to local causes (such as uncleanliness), and to skin-eruptions, such as herpes, eczema, impetigo; and partly to dyscrasia, acute exanthemata, tuberculosis, scrofulosis, or syphilis. The oxyuris vermicularis was also a frequent cause. But these causes can, according to Pott, only be occasional; generally, he believes, there is a specific transmissible disease. He has observed cases in which several children of the same family were affected, in which the mother and father were affected at the same time. The father had, in this case, either suffered with gonorrhœa before, or was at the time suffering with it. Epidemics occur in hospitals, and even in boarding-schools. Cases in which defloration was the way of infection were rare. He mentions that in many countries the superstition prevails that a man infected with clap can be cured if he have intercourse with a virgin. Dr. Pott is of opinion that the poison of gonorrhœa is the sole cause of vulvo-vaginitis. Both he and others have demonstrated gonococci. Children, he says, acquire clap (1) directly through coitus, or contact with a penis when there is a gonnorhœal urethritis; this must occur rarely. (2) Infection may occur in the passage of the child through the vagina at birth. This must be rare, though he says it is possible; blenorrhœa would occur much more easily. After birth, in the first days of life, children acquire clap from the infected finger, from sponges, from linens, or the child may get it by sleeping with its parents, if they have it; through contact with soiled bed or body linen; children handle and play with their sexual organs, and in this way the child may infect herself. Again, several children may sleep together, and in this way reciprocal infection occur. He does not think that vulvo-vaginitis is a symptom of syphilis, but admits the possibility of a double infection being present in the same case—congenital syphilis and acquired gonorrhœa. As to treatment, he advises corrosive sublimate and iodoform.—*Deutsche med. Wochenschrift*, July 26, 1888.

Acrania.

Dr. J. F. Lockwood, of Batavia, Ill., reports, in the New York *Medical Record*, August 18, 1888, the following case: "Mrs. S——, a native of Sweden, primipara, gave birth to an acephalic female child. It was still-born, and there was no response to the artificial efforts, yet quickening was felt to the last by the mother, and I myself, while manipulating, felt muscular effort on the part of the child. It seemed to be at full term, *i. e.*, otherwise fully developed. The peculiar features of the case were as follows: First, as to the conduct of delivery. I could not feel the parts of the child with my finger in the vagina, although the os was well dilated and the bag of waters was prominent and easily ruptured. The amount of amniotic fluid was very great. After the rupture of the membrane, the breech presented and was delivered at the end of four or five hours. The cord was coiled once around the right leg, just above the knee. I anticipated trouble in delivering the head, but found no opposition to its passage, for this stage was soon completed, and the explanation came with it. There was no skull and no scalp. The hemispheres were small and unprotected, and the outer integumentary covering to the spine was also lacking. I suppose the removal of the pressure from the exposed and partly-developed cerebrum was the cause of death."

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.25**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

YELLOW FEVER.

Amid the alarm and distress caused by the present outbreak of yellow fever at Jacksonville, Florida, it would be well, we believe, for medical men to exert themselves to allay the fears of their fellow-men as much as possible. When this disease breaks out, the number of its victims is increased by panic and lessened by calmness and common-sense. Yellow fever is an infectious disease and not a contagious one. There is evidence enough that all persons exposed to the conditions which give rise to it are liable to contract it; but there is no good evidence that those who are at a distance from the place where these conditions exist are liable to contract it from persons already suffering with it, or from clothing or other *fomites*. Persons who have had experience in yellow fever epidemics are generally agreed that the disease is not contagious in the true sense of the term, and it is important that medical men should not allow this fact to be lost sight of. Unfortunately, however, we cannot see much evidence that this view is held by some who might use it with the greatest effect. As an illustration of our meaning, we would refer to what is now going on in connection with the U. S. mails. Under order from the proper authorities, the letters coming from Jacksonville are now subjected to what is called a process of disinfection. This process is utterly useless, if it is regarded as a process of disinfection, and furnishes a wonderful example of the absurdities sometimes practiced by health authorities. If the futility of a process of disinfection is recognized by those who have ordered it, it can be justified only on the ground that it is intended to allay the popular dread of yellow fever. But it would be far better, in our opinion, to teach the community that there is no reason to believe that yellow fever can be communicated by means of a letter, than leave them in error on the point, and dupe them with a show of disinfection, the hollowness of which is in danger of exposure at any moment.

It is to be hoped that the present outbreak of yellow fever will yield some useful fruits of knowledge in regard to its nature and operations, and that those who are bravely combating it will be able to clear up certain points which are still confused in the minds of medical men. Among these points none is more important than the mode of its communication; and we heartily wish that those who can speak from personal observation would unite to impress on the minds of the community the fact that yellow fever is not a contagious disease, and that those officials who have charge of the public health would shape their protective measures so that they would not lend support to the erroneous view that it is contagious. This, we think, would do more good than all the fumes of sulphur, or the detonations of artillery, with which medical men or the laity may endeavor to stay its devastating march.

PREVENTION OF CONCEPTION.

There is no subject in the wide domain of medical practice which is of more general interest in civilized lands, or which demands more discretion in its consideration, than the question of the propriety of preventing conception in the state of wedlock. In most English-speaking countries, this subject is rarely discussed, and, when it is discussed, this is done with considerable misgiving as to the opinion in which not only the argument but also the arguer will be held by wise and conscientious men and women. This misgiving is a sort of testimony to the comparative chastity of English-speaking countries; but it is possible that it is somewhat exaggerated, and that even so delicate a subject may be regarded with too much timidity by those whose duties often bring them face to face with disagreeable and even dangerous situations.

No medical man of any experience can fail to know that the propriety and feasibility of preventing conception engages, at some time or other, the attention of a large proportion of married people in civilized lands, and there is danger that an undue dread of discussing it frankly in medical circles may deprive medical men of the means of properly directing a disposition which cannot be ignored, and which, in the present state of human nature and civilization, it seems impossible to eradicate.

The arguments of the disciples of Malthus for restricting the number of children in a family, and of those who accept part of his opinions, although they reject others of them, are founded principally upon economic considerations. But there are other considerations which deserve to be entertained. Among these are some which have been either hinted at, or openly stated, in certain of the contributions published in the REPORTER during the past twelve months, on the "Conjugal Question." The hardships alluded to in those papers and letters devolve upon women as a direct consequence of the practice of monogamy, and are part of the price paid for its manifest blessings. One of these hardships is the liability to too frequent child-bearing. This is perhaps the most serious reason why such complaints are made of the excessive indulgence of the sexual appetite by men, as were communicated to the REPORTER last year. It is not because women have no corresponding inclination to sexual intercourse in itself which makes many of them regard it as a burden or a curse, but because they can rarely rid themselves of the dread of its consequences. To them it always means the possibility of pregnancy, of months of discomfort and often of shame, of the perils of child-birth, of the cares and anxieties of motherhood, and of burdens and responsibilities which are at best only shared by the men. The mere economical considerations which have seemed to many thoughtful men sufficient to justify restriction of the number of children born in wedlock have less weight with women, but the dangers and discomforts of which we have just spoken are, with rare exceptions, ever in their minds, and the question of preventing conception is one which demands chaste, to be sure, but also fearless, consideration as an act of humanity to those who, in our day, bear too large a share of the curse of Eve.

Besides this, however, the limitation of child-bearing is a matter which has an incalculable bearing upon marital and family felicity. The woman who lives in dread of her husband's sexual appetite cannot satisfy him as a wife, and, with this poison in her life, must find it hard to be a kind and wholesome mother to her children.

It will not do to cover up such a state of affairs with euphemisms. Those who know what goes on in the privacy of many a home, as physicians only know it, know that the dread of pregnancy and child-bearing has wrecked the peace of thousands of households, and led to steps of desperation where those who knew less about it never suspected them, or were utterly ignorant of their motive.

Impressed with this fact, we invite our readers to discuss in these pages, as wise and thoughtful physicians, the importance of the prevention of too frequent conception. Opinions may differ as to what constitutes too frequent conception, or as to the desirability of interfering at all with the course of nature in sexual matters, but we believe that a candid study of the subject is an urgent need of the present day, and hope that the REPORTER may do something toward meeting this need, difficult and delicate as the task may be.

TREATMENT OF GENERAL PERFORATIVE PERITONITIS.

The progress that has been made in the last ten years in the knowledge of inflammatory disease in the region of the cæcum is most gratifying, and there is reason to believe that, in the near future, differential diagnosis and treatment, as applied to diseases in this region, will be based upon well-recognized and satisfactory data. It is not our purpose at this time to discuss the radical differences of opinion among operating surgeons as to the proper time and character of the operation for perityphlitic abscess. This difference of opinion, we think, is largely due to conflicting views as to the morbid anatomy of these abscesses, as to whether they are properly classed as cases of circumscribed purulent peritonitis or of true abscess located external to the parietal peritoneum. With regard to a different though allied class of cases, where general or rapidly-spreading peritonitis follows perforation of the appendix or cæcum, or the rupture of a perityphlitic abscess, with the escape of pus within the cavity of the peritoneum, there appears to be general unanimity of opinion. The prognosis of these cases under medical treatment is fatal, and it is only by prompt resort to abdominal section and proper treatment of the conditions found that any reasonable hope of recovery can be offered. The first abdominal section for peritonitis due to non-traumatic perforation of the stomach or intestines was done by Mikulicz in 1880, and reported in 1885; and Weir, in 1887, was able to collect only fourteen additional cases. The operation, from this indication, is but applying to intestinal surgery the rule which has been followed by gynecologists since Thomas Keith had the courage to operate with success, during the course of a purulent peritonitis, and remove the cause—an ovarian cyst, in which suppuration had been set up by tapping; or extending to spontaneous perforation of the intestine that treatment which is universally conceded to be demanded in traumatic perforations of the bowel.

The recent successful case of Sands, reported in the *New York Med. Journal* of February 25, 1888, brings up this subject anew; and the fact that Sands, well known as an opponent of early operation in perityphlitic abscess, strongly urges the necessity of early resort to laparotomy in perforative peritonitis is at least worthy of consideration. The question as to whether median or lateral section is best in these cases is still debatable. The greater ease with which the median section can be made, the less amount of hemorrhage, and the advantages offered for draining Douglas's cul-de-sac would influence most operators; but, should tumefaction in the region of the appendix be present, indicating circumscribed collections of pus in addition to the general peritonitis, the lateral operation would probably offer superior advantages. Perforations of the cæcum should be closed by Lembert sutures. The same treatment is applicable to perforations of the appendix, but preferably this worse than useless organ should be amputated. This has usually been done by ligating it and cutting it off. It would seem better to close the lumen of the stump by Lembert sutures rather than to use the ligature. Other operative treatment of the bowel will seldom be indicated. After the closure of perforations, the sheet-anchors of success will be free irrigation

and drainage. Valuable time should not be wasted in too vigorous sponging. Perhaps Senn's hydrogen-gas test will prove useful in some cases when an examination of the appendix and cæcum fails to demonstrate perforation.

PHYSIOLOGY AS SHE IS WROTE.

There lies upon our table a little book which has such an appearance of having been published with a commendable object, that we trust the author will forgive us if we use it to point a moral which we believe to be of importance. At the same time, we trust that our readers will see that our desire to make the book of service in a different way from that which the author intended does not require that we should expose his person as well as his work to the gaze of others.

In the REPORTER, April 21, 1888, we called attention to the amusing errors of a translation which had been offered for publication in this journal, but the book before us presents more numerous and as amusing errors by one who wrote in his native tongue.

Since Mark Twain brought again to notice the little "English as She is Spoke," we have seen nothing to compare with this. It appeals to physiologists and physicians; to printers and proof-readers alike. Every page is studded with typographical and grammatical blunders, which are only equalled by the errors of the text, considered scientifically. An author and a publisher so admirably matched are rarely brought together for our delectation. Nouns singular are more commonly given verbs in the plural (or *vice versâ*) than not.

The possessive case was evidently never heard of by either author or proof-reader. There is the most wonderful use and disuse of capital letters—and the abbreviations! The author intended helping us out by prefacing the book with a list of abbreviations, but he tabulated only a small portion of those used. However, we should be glad to know that, in the body of the work, M. O. stands for "Medulla Oblongatta"; P V for "Pons Varoli"; C. S. for "Corpora Striatum"; C C for "Corpus Coilosum," etc., etc. But what lexicon will help us out with such a sentence as this: "The P—— C—— are the articular C—— of bone, the *Costal* C——, of the Larynz and the Nose. White Fibro Cart—— has matrix converted in part into white fibrous tissue. This W. F. C—— are the interarticular cartilages, etc."

A new hint is given the surgeon in the explanation that Torticollis is "rye neck," and horsemen will hereafter profit by the suggestion that "in the horse the presence of pigment in the hoof is an evidence of sagacity, such an animal being trained more easily than one having light hoofs." We have been puzzled to know how the "auricular ventricular opening" could be "closed by a spinster motive." (The word *sphincter* has been a great *pons asinorum* for author and proof-reader, *e. g.:* "The mammary glands are contracted by a spincter muscle at the nipple, which muscle has the same relative function as the spincer aui.") The following sentence may interest physiologists: "The diaphragm has a fixed position on the viscera. from which as a center it acts to pull the ribs up and outward, thus enlarging the thoracic space during inspiration. Where there is no diaphragm, the breathing is done by the nearest muscle, namely the abdominal or perineal. When a plaster paris jacket is applied the breathing is done by the perineal alone."

Our author has the greatest fondness for protoplasm, and uses the word on every possible occasion. "Some protoplasm," he says, "is born tied, and cannot break up the proteids, and emaciation results." An explanation of leanness and obesity is entitled "SEXUAL CONDITION. When the sexual condition is aroused, the protoplasm lingers in the region of the genitals, and the animal consequently grows poor. Castration tends to fatten, because the sexual condition is now destroyed. During lactation the

proteids become milk by the action of protoplasm in the mammary glands."

The ophthalmologist will find in this book more amusement than other specialists, though the otologist, the gynæcologist, the laryngologist, etc., will not miss their share. For example, we find that "an emmetropic eye is an impossibility," that "the distant point of accommodation" arises from "overrelaxation of the ciliary." "Myopia always becomes worse, you never see distinctly. It is caused by overstimulation of the brain and overcontraction of the ciliary muscle, which makes the lens convex." Astigmation "may occur in the vitreous humor." Under the head "Eutopic Phenomena," we are told "these are those which occur in the eye." "A line from the *mascula lutea* through the corner constitutes the visual axis," and "a line from the spot of mariot through the corner constitutes the optic axis."

As to the ear, the author says: "The sensual apparatus is the same as in all the organs of sense"; and the "cochlear" is described thus: "The two canals join at the apex of the cochlear so that an insect passing along the one canal cannot return by the other but must return by the same." "The stapedias regulates the amount of air entering the int. ear and prevents injury from pressure." "The cochlear is supposed to be connected with musical notes." "Noises in the air are painful and depressing."

The section on the larynx ("a respiratory passage like the lungs") is particularly rich. We cannot forbear quoting the explanation of whispering when "a person is aphoseate." "He whispers because he cannot take advantage of the resonance in the frontal tissues from which the resonance is derived. Extirpation of the larynx will destroy speech but the lips can be cultivated, and in this way some persons are very skilful, suspending the action of the cords, at pleasure."

In speaking of respiration, we find the curious statement that the "air of Respiration" is divided into "Tidal air, amounting to 20 cub. in. *per hour;* Complimentary, 110 cub. in. per hour; Reserve, 100 cub. in per hour; Residual, 100 cub. in an hour," while the explanations of "exophtyalmic goitre" and of the pulse are among the wonders of the book.

We might extend our quotations and include what the author calls "a few nervous points"; but we must forbear. Enough has been quoted from this remarkable book to show that something more is needed for one to become a good author than that he should make a book out of notes taken at medical lectures, and attempt to supplement the wisdom of his teachers with ideas which he modestly thinks better than theirs. Except as a source of amusement, this volume has no claim to professional notice; but it may serve a useful purpose if it warns those who aspire to such notice against an error to which the language of Charles Lamb may be applied, who said, of the owner of a certain sort of faculties, that "They seldom wait to mature a proposition, but e'en bring it to market in the green ear."

—The Congress of American Physicians and Surgeons meets in Washington next week. In this connection it is worthy of note that a large number of physicians arrived in New York City, Saturday, September 8, from Liverpool, in the steamship Umbria. Among them was Sir William MacCormac, Chief Surgeon of the St. Thomas Hospital, London, which stands on the banks of the Thames directly opposite the Houses of Parliament. With Sir William, were five other noted English physicians, including Dr. Arthur Edward Durham, Senior Surgeon of Guy's Hospital, London, and author of "The Physiology of Sleep"; Dr. Reginald Harrison, Chief Consulting Surgeon and Lecturer at the Liverpool Royal Infirmary; Dr. William Miller Qrd, President of the Medical Society of London, and Mr. Victor Horsley, who has contributed much to the surgery of the brain and spinal cord. Sir William MacCormac says he came here more for rest than anything else, but he will attend the Congress in Washington. Drs. Durham and Harrison became the guests of Dr. Sayre, of New York.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

HYGIENE FOR BASE-BALL PLAYERS. By A. H. P. Leuf, M D, Director of Physical Education at the University of Pennsylvania, etc. 135 pages, 12mo. Philadelphia: A. J. Reach & Co., 1888. Price, 50 cents.

Nothing indicates more significantly the hold which the game of base-ball has taken upon the people of the United States than the amount of literature devoted to it. No daily paper is regarded as complete which fails to chronicle the issues of the daily contests all over the country during the playing season, and magazine articles and books are appearing from time to time to inform the public of the "points" of the game, and players of the principles involved in it. One of the best which we have seen is the one before us, which is intended to give base-ball players scientific instruction in regard to the way in which the various parts of the body act in efficient work. It gives a brief account of the anatomy of the bones and muscles used, a very complete description of the methods employed in modern pitching, and many directions for securing the best results as a player, for avoiding injury, and for treating injuries when they occur. It is written by a physician who is experienced in physical education, and who has, by observation and experience, learned what are the needs of base-ball players. His book may be heartily commended to the attention of all who are interested in our national game, and we believe it is calculated to be of great service to all who take an active part in it.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

The Orthopædic Treatment of Paralysis of the Anterior Muscles of the Thigh. By A. B. Judson, M.D., New York. From the *Medical Record*, February 4, 1888. 8 pages.

Dermepenthesis; Animal Skin-Grafting. By G. F. Cadogan-Masterman, M.D., Stourport, Wales. 7 pages.

Vesico-Vaginal Fistula. By Reuben A. Vance, M.D, Cleveland, Ohio. From the *Cleveland Medical Gazette*, February, March, April, and May, 1888. 35 pages.

Fifty Aphorisms in Pregnancy. By E. J. Kempf, M.D., Jasper, Indiana. From the *American Practitioner and News*. 16 pages.

Certain Facts Regarding Fertility, Utero-gestation, Parturition, and the Puerperium in the So-called "Lower" or "Laboring" Classes. By George Woodruff Johnson, M.D., Washington, D. C. From the *Amer. Jour. of Obstetrics*, May, 1888. 19 pp.

—This pamphlet of Dr. Judson's is principally occupied in describing an ingenious and very simple form of splint which he has designed for cases in which involuntary flexion takes place at the knee-joint as a result of infantile paralysis of the extensor muscles of the thigh. The simplicity and cheapness of the apparatus recommend it strongly to professional favor, and its utility seems to have been demonstrated in Dr. Judson's practice.

—Dr. Cadogan-Masterman, having experienced the difficulty of obtaining suitable human material for skin-grafting, tried, in January, 1885, the effect of using the skin of the rabbit for this purpose. The result, an entire success, and he has now used this material in four cases, and recommends its adoption by other surgeons. From his experience, he thinks the skin of the young wild rabbit the best for the purpose, and he maintains its vitality by the application of moist heat after its application. His method was so successful in his hands, and seems to be so rational, that we hope to be able to present it in full to our readers shortly.

—The writings on vesico-vaginal fistula are not yet quite as numerous as the sands of the sea, but they can hardly be called few; still, a paper as carefully prepared as this of Dr. Vance, and bearing so many marks of intelligent observation and skilful practice, will always be welcome. His pamphlet contains an excellent description of vesico-vaginal fistula, as a lesion, and the form of operation best adapted to cure it. The clear descriptions of the text are admirably supplemented with illustrations, and the whole would be a valuable addition to the library of any physician.

—Dr. Kempf's fifty aphorisms are sensible and calculated to be useful. As he invites dissentients to express their opinions, we may say that some experience inclines the writer to question the advisability of "hardening" the nipples during pregnancy with an astringent solution, and to prefer softening them with some simple emollient. Again, while we cannot gainsay the truth of his fifth aphorism, we think it would be easy to abuse the permission it grants, and would suggest that this may not be stretched without great danger of bringing on an abortion.

—Dr. Johnson's paper contains a very interesting study of the conditions he found in three hundred women belonging to the laboring class, in reference to the exercise of the procreative function. The facts he notes indicate that certain notions commonly entertained in regard to women of the laboring class are erroneous. For instance, that they are usually fertile and prolific above well-to-do women, and that they suffer more than the latter from lacerations and other injuries of the genitalia during labor. Other important generalizations may be made from his address, which deserves the careful attention of all who are interested in its subject.

Literary Notes.

Harper's Monthly was the pioneer among magazines which developed the art of engraving to the high point which it has attained in America. This development has now gone so far that it is hard to see how it can be carried any further. A glance over recent numbers of *Harper's Magazine* shows the most wonderful advance from the productions of the graver in earlier years, and furnishes most interesting evidence of the progressive character of its literary contents. It is saying a great deal to say that it maintains its position in face of the intense competition of some of its rivals, and still stands at the head of the illustrated magazines of America.

CORRESPONDENCE.

Strongulus Gigas.

TO THE EDITOR.

Sir: I have been very much interested in the case of "Strongulus Gigas" published in the REPORTER of August 25, and suspect it is open to an interpretation different from that given by the writer. As he says, such cases are of extreme rarity, so much so that it is doubtful if any genuine case of the occurrence of this parasite in man has been recorded. The *strongulus gigas* as found in animals is much larger than the supposed worms in the present case, attaining a length of three feet. In this case, the enormous size of the right kidney—weighing two and one-half pounds, its resemblance to a fatty kidney, but with no trace of kidney tissue, together with a similar change in the other kidney and the liver, point unmistakably to new growth, perhaps carcinoma. The "worms," according to this view, were blood-casts, such as are passed frequently by patients similarly affected. During the past winter, several such specimens were exhibited before the Philadelphia Pathological Society, one set, if I mistake not, from a case of carcinoma of the kidney.

Hoping this may throw still more light on the subject, I am

Yours truly, GEORGE DOCK.

Manayunk,
August 26, 1888.

Herpes Ophthalmicus.

TO THE EDITOR.

Sir: When reading the account of Dr. Wheelock's case of herpes ophthalmicus, in the REPORTER, December 3, 1887, page 752, I was struck with the similarity of symptoms and sufferings to those experienced in my own person. Though the disease is common here, I had never seen a similar case, nor could my associates remember one; and, when able, I intended to report it. Professor Wheelock's patient was ten years younger than I am, and was a robust man; but, if his sufferings were intolerable, mine were more so, as, during one of my paroxysms, my family thought me past reanimation.

Most authors treat of herpes too superficially; one who has not experienced an attack cannot appreciate its gravity. When it occurs over the cardiac region, death, in my experience, supervenes on or about the fifth day. I have two chronic cases whose duration exceeds over twelve years, and whose neuralgic pains and itchings I cannot relieve. I am using antipyrine, recommended by Dr. Germain Sée, before giving it to my patients.

On April 25, 1887, I felt, on awakening, slight nervous twitchings, branching out from a small dry point on the left upper lid; the twitching was just enough to attract attention. The spot resembled those produced by the exudate of the "matta," an insect pest prevalent at that period of the year. I paid no attention to it during the day. The next morning, my daughter noticed two fine white pimples. The day was passed with an occasional twinge of pain, augmenting in the evening, and branching out over the forehead and temporal region. The next morning, the eyelids were red and swollen, the eye injected; the pain was intolerable, and an eruption extended over the head, face, lips, and into the mouth. There was no eruption nor any inflammation to the right of the median line. There were paroxysms of pain in which the pain extended down both arms to the tips of the fingers; down the spine to the lumbar vertebræ, thence to the toes of both feet, causing numbness. This was succeeded by a pricking sensation, which disappeared under the use of friction. The arms were longer than the other parts of the body in returning to a normal state.

On the sixth day, the viscid serous exudate from a few large pimples, mostly confined to the hairy scalp, lips, and mucous membrane of the upper part of the mouth, had an offensive odor characteristic of the disease; one pimple on the lid was elongated, and, on the eighth day, had formed a thin dark crust, depressed below the surface, and, like the rest, was very tenacious and leathery: it was detached on the twenty-fifth day, with scissors. The face and forehead were covered with fine pimples, which were crusted on the twelfth day. From the eighth to the sixteenth day, the paroxysms numbered ten or twelve in twenty-four hours; then they abated to four or five, disappearing on the twenty-fifth day. They were succeeded by very small ones; when falling asleep, they were still felt, but not every night; they did not pass beyond the fingers. No sensation was felt in the spine, as at first.

The eyes continued to suppurate until late in August. Suppuration was followed by a viscid exudate, continuing until late in February. This was in turn followed by a watery exudate, lasting until May and being sufficient to glue the eyelids during sleep.

The latter still continues, but is about disappearing. A deposit of lymph that covered the cornea was gradually removed by molasses, dropped in twice daily. (Highly recommended to me by Dr. V. Mott, in 1847.) Adhesions were removed by alternate use of eserine and atropine. Eyelids feel stiff, vision is incomplete, owing to a barely perceptible turbidity in the anterior chamber, which prevents me from reading any print.

At first I used cocaine liberally and also solution of boric acid. Iodide of potash was used to mitigate the pain, with slight benefit. Quinine and the most noted tonics were also used, together with electricity, which is being repeated. As Drs. Mabano and Barrios early gave up all hope of saving the eye, I adhered for a long time to the use of powdered boric acid, together with a solution of the same as an antiseptic, and have saved the eye, although it still troubles me. Now, if you can suggest anything to relieve the *itching*, I think the sight might be relieved immediately after.

Yours truly,

EARL FLINT, M.D.

Rivas, Nicaragua,
August 7, 1888.

NOTES AND COMMENTS.

Urethral Discharges.

At the meeting of the Ontario Medical Association, June 13, 1888, Dr. Grasett read a paper on urethral discharges (*Canadian Practitioner*, July, 1888). After referring to the frequency with which such cases are met and the depressing mental effect the condition often has upon the patient, he divided the subject into sections, according to the nature of the discharge. 1. When the discharge is the result of a catarrhal condition of the urethra—urethritis. This urethritis may be: (*a*) Simple. such as that set up by leucorrhœal discharge, excessive or violent coition, or mechanical irritation. This is usually less severe and of shorter duration than (*b*) specific urethritis or gonorrhœa. Whether or not this specific inflammation is always due to the presence of gonococci, cannot be regarded as proved. Experiments have failed to establish that it can be induced by injection into the healthy urethra, and it has not been found possible to inoculate animals with gonococci. Notwithstanding these facts, the almost constant presence of gonococci suggests that they are possessed of causative properties.

The plan of treatment found to be most useful might be summarized as follows: Rest in bed; cleanliness, secured by frequent passage of urine, or by injecting hot water. The patient should be instructed to allow the penis to hang in a natural position, so as to permit the discharge to run out; or a dressing of salicylic gauze might be placed loosely over the end of the penis and covered with a rubber bag. The diet should be light and unstimulating; alcohol and tobacco must be avoided. Alkalies may be given, to keep the urine neutral or slightly alkaline. Injections, except of hot water, are harmful in the first or acute stage. The injections frequently given by chemists do great harm. In the late stages, sulphate and sulphocarbolate of zinc are beneficial in dilute solutions; so, also, is nitrate of silver.

2. Chronic discharge or gleet sometimes persists after an attack of gonorrhœa, in spite of treatment, both internal and external. An error in diet, or indulgence in alcohol or tobacco, will often cause a return to the catarrhal stage. The pathology of gleet probably depends upon the fact that the inflammation, which commences in the mucous membrane, spreads to the submucous tissues, and causes a thickened and granular condition of both. If a stricture is present, it should be dilated. The injections used should be mild and slightly stimulating astringents, and should be frequently changed. Caspar, of Berlin, recommends a combination of mechanical and chemical therapeutics. He uses nickel-plated bougies with grooves, into which he pours a medicated paste, which melts when the bougie is inserted into the urethra. He has used iodoform, zinc, resorcin, and other drugs, but has had the best results from the use of this formula:

Olei theobromæ	100 pts.
Argenti. nit.	1–1½ "
Bals. copaibæ	2 "

No bad effects have been noticed. Improvement begins at once, and the discharge, under the microscope, soon shows a diminution in the proportion of pus-cells.

3. Prostatorrhœa was first accurately described by Dr. S. W. Gross, of Philadelphia. It consists of a clear glairy mucus from the prostate, most frequently seen after straining at stool. It comes from the acini of the gland, and is increased in quantity by disease of the rectum, masturbation, hard riding, etc. Several instances of this condition were cited, illustrating the good results which followed treatment by tonics and the local use of nitrate of silver.

4. Spermatorrhœa, or flow of semen, unaccompanied by sexual excitation or orgasm, is used by quacks and empirics to include nocturnal emissions, which, unless excessive, are an indication of health rather than of disease. If, however, they become too frequent and are followed by depression, they are pathological. The causes are, among others, hyperæsthesia, or irritation of the genitals, inflammation of the prostate or urethra, phimosis, etc. The treatment should be largely hygienic. Avoid alcohol and tobacco, empty the bladder the last thing at night and first thing in the morning, give light diet, keep the bowels loose, and abstain from irritating exercises, such as riding on horseback. Bromide of potash often acts beneficially. If the prepuce is long, circumcise it; if there is rectal irritation, as piles, fissure, etc., appropriate treatment must be applied for them. Passing large bougies, and the local application of nitrate of silver, gr. x or xx to one ounce, are also useful. The depressed mental condition of the patient must not be neglected, as very much depends upon his intelligent co-operation in the treatment.

Use of Creoline as an Intestinal Antiseptic.

Dr. Hiller, of Breslau, in a communication in the *Deutsche med. Wochenschrift*, July 5, 1888, recommends creoline as an intestinal antiseptic and parasitic. Promptness and certainty of action, freedom from danger in that it does not act either as a poison or as an irritant when taken internally, make creoline, he says, the ideal antiseptic for diseases of the stomach and intestinal canal. Dr. Hiller has observed the good effects of creoline in meteorism of whatever cause—stenosis of the bowel, typhlitis, enteritis, habitual atony of the bowel, with constipation, and typhoid fever. The same never-failing action was demonstrated in flatulence, which accompanies acute and chronic colitis, in the fulness and swelling of the epigastrium after food, as a result of disturbances of gastric digestion, and especially in the putrid decomposition of the contents of the bowel in chronic enteritis and colitis. Colitis, likewise, when creoline is used, combined with washing out the stomach, accomplishes brilliant results in dilatation of the stomach, as a result of stricture of the pylorus, overcoming the development of gases and the distressing symptoms occasioned by them. Its prompt and certain checking of the processes of fermentation is also proved in acute catarrh of the stomach, in simple diarrhœa, and in cholera morbus. Hiller employed creoline in doses of from 4½ to 15 grains, generally given three times a day, after meals. On account of its bad tarry taste, he gave it only in strong gelatine capsules. He regards the administration of creoline, as indicated in dysentery, both internally in doses of 7½ to 15 grains, three times daily, and in the form of clysters, of a strength of 15 or 45 grains to 16 fluid oz.; also in carcinoma of the rectum, as a wash, and in cholera morbus and cholera nostras. He suggests its use in Asiatic cholera. Hiller has also employed creoline in one case of tænia solium, and in one case of oxyuris vermicularis (15 grains in gelatine capsule, three times a day) with prompt effect. He says that the drug cannot be employed in practice among children, because it can be taken, in sufficient doses to be active, only in gelatine capsules. In larger children, small capsules containing from 1 to 1½ grains, preferably with honey, may be given.

Hysterical Spasm of the Œsophagus in a Young Child.

Dr. B. D. Foster, of Chicago, in a letter to the *Medical Record*, July 21, 1888, says: "I was called one day in great haste to see Mary C., ten years of age, who was said to be choking to death, and found her complaining of great pain in her throat, which she was grasping and begging her mother to rub for her. The mother, attributing the trouble to 'a worm in her throat,' was vainly endeavoring to pour down a dose of Jayne's vermifuge. The child was unable to swallow, the fluid regurgitating into a handkerchief held in front of her mouth. I immediately administered a hypodermic injection of morphine sulph., gr. one-sixteenth. Although complaining bitterly of the pain induced by the fluid being forced beneath the skin, her face immediately assumed a happy expression, and she laughingly declared she was cured the instant the needle was withdrawn, and, obviously, before the solution could have been absorbed. In a few minutes she was laughing and playing in her usual health. The history showed that her mother had been subject to various neuroses (supposed to be hysterical), and that two other relatives were idiotic or imbecile. I diagnosed hysterical spasm of the œsophagus. The youthfulness of this subject, and the immediate relief afforded by the prick of a needle, are not entirely devoid of interest."

The Time of Death.

While Dr. Munk's charming little book upon Euthanasia is still fresh in our memory, it is curious to note, says the *Lancet*, July 14, 1888, that M. Brouardel has been recently lecturing upon the precise moment of death, considered from a medico-legal point of view. It is with a feeling of some surprise that we learn that he wholly rejects as signs of death both cessation of respiration and arrest of cardiac pulsations. The most recent observations upon a decapitated body showed that cardiac movements persisted an hour after the head had been severed, and on these grounds, as well as on account of the temporary arrest in fainting, he holds that the cardiac movements afford no certain criterion for gauging the precise moment of death. That the spinal cord has comparatively little influence upon the heart's action was well shown by experiments upon two dogs; the one was completely decapitated, in the other only the soft parts of the neck were divided, and yet the time that elapsed before cessation of cardiac movements was practically the same under both conditions.

Elixir of Theine Hydrobromate.

Mr. J. W. England, of Philadelphia, at the meeting of the College of Pharmacy, May 15, read a paper on theine, in which he states that, of all the possible salts of theine—the term is here used synonymously with caffeine—the hydrobromate would, he says, seem to be the one whose chemical character would most consistently give the best therapeutical action. The sedative alkaloid theine, being in combination with the sedative hydrobromic acid, the action of theine hydrobromate should be doubly happy. He admits that the percentage of the acid is small, but, all things being equal, thinks it should, theoretically, be the best. Reasoning on this basis, Mr. England constructed an elixir of theine hydrobromate, which was tried medicinally, and the results obtained would seem to justify the highest expectations formed in regard to it. The formula used is as follows:

Take of:

Theine	℥ iss
Dilute hydrobromic acid	f℥ i
Water	f℥ i
Elixir of orange	q. s. ad Oi.

Dissolve the theine in the water and hydrobromic acid with the aid of heat, filter, and add the orange elixir. Dose: 1 to 3 teaspoonfuls The product is a clear, transparent, water-white liquid; pleasantly bitter in taste; almost neutral in reaction, miscible with an equal volume of alcohol without precipitation. Each teaspoonful contains one grain of anhydrous theine hydrobromate (C_8 H_{10} N_4 O_2 HBr.).—*American Journal of Pharmacy*, June, 1888.

Abscess of the Liver, due to Actinomycosis.

The *Lancet*, June 30, 1888, states that a patient, a commercial traveler twenty-five years old, who had never been abroad and had enjoyed good health, and who was suffering from actinomycosis, was recently under the care of Dr. Payne, in St. Thomas's Hospital, London. He first complained of severe pain over the front of the right lower ribs, three days before admission, which was on May 4. The pain was worse on coughing or breathing, and on attempting to lie on his left side. The hepatic dulness extended upward to the fifth rib in the nipple line, but the lower border could not be felt below the ribs. There was a little albumin present in the urine, and he suffered from slight cough, with expectoration. The cough and expectoration became less, but the pain continued severe, and was subject to exacerbations. The temperature, seldom below 100°, generally rose to 102.2°–103.6° daily. About May 20, slight bulging of the right lower ribs, in front, was noticed, and there was a little friction audible over the fourth interspace close to the sternum; dulness reached to the fourth rib at the nipple. On the 23d, thick pus was withdrawn with a hypodermic needle at a depth of about one inch and a half, in the sixth space, about in a line with the nipple. On the 26th, Mr. Battle cut down in this space and stitched the diaphragmatic pleura to the costal pleura, opening the abscess four days later. Full antiseptic precautions were taken. About four to five ounces of thick pus were evacuated. In a few days the pain was relieved, and the temperature, on the whole, became lower; but on June 1 the temperature rose to 103°, with rapid breathing, and there were signs of fluid in the right pleura, with delirium and vomiting. On the 6th, the pleura was aspirated, and forty-nine ounces of purulent fluid removed. The patient died on the following day. At the autopsy, made by Dr. Hawkins, there was a small emptied cavity in the liver, with surrounding deposits of actinomycosis; empyema on the right side, having no communication with the wound leading to this cavity; and purulent pericarditis. The other organs were healthy.

The Emperor and the American Physician.

Of the late Emperor Frederick, it is told by the New York *Post* that, while he was in London for the Queen's jubilee, Sir Morell Mackenzie introduced a noted American doctor to him. After a careful examination of his throat, the imperial patient, in his usual cheerful manner, inquired: "I suppose an imperial throat is very much like that of other mortals?" "Well, sir," came the quick reply, "we will try and make it so, at any rate." The then Crown Prince thoroughly appreciated the quick Yankee wit, and, striking his broad chest, said: "But this is all right, is it not?" The Yankee gravely looked the splendid proportions of the illustrious patient up and down, and then deliberately drawled out: "As for the rest, sir, you would make a good American." Fritz's merriment was great, but the German doctors present were aghast at such levity.

Influence of Nicotine upon Pregnancy.

At the recent meeting of the Society of Practical Medicine of Paris, July 12, 1888, M. E. de Pradel said that he recently had had a patient who, since her eleventh year, had been engaged in a tobacco manufactory, and who, within three years, had had one abortion at two months and two premature labors at eight months, the children presenting signs of having been macerated for several weeks. Not finding any signs of syphilis in the husband or wife, he asked himself if the cause could be a certain degree of poisoning with nicotine. In spite of divergent opinions of writers, he felt called upon to advise the patient to quit her work in tobacco for good. He says he is induced to believe in nicotine as a cause of abortion from the case related by M. Quinquaud, in which a patient who had had three abortions during her stay in a tobacco manufactory, after giving up her work there had three healthy children.—*Bulletin Médical*, July 15, 1888.

Philadelphia Polyclinic.

The Philadelphia Polyclinic has had a larger summer class of physicians in attendance this year than in any previous year. The prospects of this institution, the only one for post-graduate instruction in Pennsylvania, were never brighter. A number of bequests, one of $5,000, have recently been received. An increase of ward capacity will soon be urgently needed.

NEWS.

—Dr. A. B. Hirsh has removed from No. 2130 Master Street, to No. 1730 Girard Avenue.

—Dr. Kratschmer has been granted the title of Professor in the University of Vienna.

—Dr. Gaffky, of Berlin, has been appointed Professor of Hygiene in the University of Giessen.

—Ten cases of yellow fever and one death were reported September 7, at Macleny, in Baker Co., Florida.

—A disease said to be dysentery has been epidemic in Presque Isle, Mich. There have been 209 cases and 8 deaths.

—Collections of money are being made in New York and Philadelphia for the yellow fever sufferers in Jacksonville, Fla.

—Dr. Franz Hofmann, Professor of Experimental Hygiene and Director of the Hygienic Institute in Leipsic University, has been made Rector of the University.

—Seventy-seven new cases of yellow fever and eight deaths were reported in Jacksonville, September 7, and forty-four cases and six deaths for the twenty-four hours ending 6 P.M., Saturday, September 8.

—Mr. John A. E. Walk, Superintendent of the Presbyterian Hospital, died suddenly, September 7. He had been superintendent of the hospital since 1871. He is said to have had symptoms of heart-trouble for some time, and seems to have died while engaged in writing a letter to his brother, Dr. James Walk, in which he complained of trouble with his heart.

—The *Med. and Surg. Journal*, September 8, 1888, says: The new wing of the Seaside Hospital of St. John's Guild at Cedar Grove, Staten Island, was recently opened with appropriate ceremonies. It measures 100 by 25 feet, and contains 64 beds, thus increasing the capacity of the Hospital one-half, so that it now accommodates 205 mothers and children.

—During the past few years, according to the *Progrès Médical*, the ranks of the medical profession in Paris have increased terribly. People in 1866, says another French contemporary, the *Paris*, were fortunate, for then only 6,506 physicians, surgeons, and druggists undertook to send them to another and a better world; now 10,360 doctors and chemists look after the Parisians, or sell them physic.

—The Philadelphia *Ledger*, September 8, 1888, says: A man who styles himself a doctor, and represents himself as connected with a mythical eye and ear infirmary in New York, has been selling large numbers of what he calls "electrical spectacles," to persons in cities and towns of New Jersey. He gets a deposit of $2 on each pair (which he values modestly at $75 each), to guarantee their return after they have effected a cure, which, he says, will follow a ten minutes' use of them every day for a short time. He doesn't guarantee his own return, however, and in time the victim can see, without the aid of glasses, that he or she is out $2, less a 25-cent pair of spectacles.

HUMOR.

THE ONLY REMEDY.—Doctor, to a *malade imaginaire:* "There is but one remedy that can save you." Patient: "And what is that?" Doctor: "Get your daughter married. You are then a mother-in-law, and they are notoriously very tenacious of life."—*Fliegende Blätter.*

THE UBIQUITOUS nickel and slot automatic delivery machine now appears in New York drug-stores, with several slots, each labeled with the name of some common complaint. The nickel having supplied the motive power, a small glass bottle is shot out containing the "appropriate medicine" for the ailment specified.

TAKING THE CHANCES.—"I w-want two g-grains of q-quinine an' four o-ounces of w-whiskey," shivered a man with malaria to the drug-clerk, "an' I'll take it n-now." "Isn't it rather a small dose?" suggested the clerk. "You seem to have got it bad." "I d-don't know but w-what it is. M-make it e-eight ounces of w-whiskey, an' I'll run the risk."—*American Druggist.*

A BOSTON SWELL recently took a trip way down on Cape Cod. He had occasion to drive from the station to his destination with a typical "Cape Codder," one of those keen but not over-brilliant-looking sons of the sea-coast. The Bostonian had noticed, as they rode along, the bleak country, with its uninviting fields and sandy strips of land, and finally said to his companion: "I don't see how you live in this forlorn-looking country. What do you raise down here, anyway?" "Wall," was the drawling answer, "we plant schoolhouses and raise men."—*Boston Times.*

AN ARIZONA MAN who subscribed for a religious paper some time ago sent a letter to the editor to stop it, in which he said: "We find *The Gila Howler*, our local paper, much livelier than your old milk-and-water affair. Besides, you haven't played a square game in your 'ads.' My wife bought a pair of the corsets you advertised, and blamed if they didn't burst in three weeks, and we use them now to mend the chicken-coop. I took half a dozen of the 'dead shot' pills you puffed up in a reading-notice, week before last, and the next day I was so sick that all the doctors in the town published bulletins about my approaching death, and the boys said I had the jim-jams. For these reasons I have determined to quit your paper and read *The Howler* only. As I know it always lies, unless it is paid to tell the truth, it can't lead me into temptation."—*American Druggist.*

OBITUARY.

JOHN LUTHER STEFFEY, M.D.

Dr. John Luther Steffey, one of the most prominent physicians and surgeons of Hagerstown, Md., died recently, in his fortieth year, as the result of an acute attack of dysentery, which had lasted about ten days. Dr. Steffey was born and brought up in Williamsport, Md. After graduation at the Jefferson Medical College, of Philadelphia, in 1870, with high honors, he practiced his profession for a few years. For the last nine years, he resided and practiced in Hagerstown, Md., where his skill as a physician and surgeon was honored and recognized at home and elsewhere. He has performed some of the most successful and difficult surgical operations in that community. He was warm-hearted and kind, possessed a fine sympathetic nature, and always had a feeling of the deepest tenderness toward his more unfortunate fellow-beings. If he had lived, it was his intention to make gynæcology a specialty, in connection with his general practice.

A few years ago, he married the eldest daughter of Mr. William Schlotlerbeck, who, with an aged father and mother, four sisters, and five brothers, survives him. His death was sudden and unexpected, and it was a great shock to the entire community. The funeral took place at his father's residence, in Williamsport, Md., on Friday, August 24. He expressed a desire to be buried in the cemetery of that place, overlooking the Potomac River, and his desire was respected. May guardian angels guard his sepulchre and may he rest in peace.

A NEW EDITION OF THE UNITED STATES DISPENSATORY. Is now binding and will be issued in a few days. *More than one-third of the book is new matter,* the whole having been rewritten and thoroughly revised. The National Formulary has been incorporated.

WHOLE No. 1647.] **SEPTEMBER 22, 1888.** [VOL. LIX, No. 12.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

References.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d Annual Winter Session will begin Monday, Oct. 1st, at 12 M., and continue 7 months

The Preliminary Session begins Monday, September 17th, the Spring Term Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y,

36th and Woodland Ave., Phila.

BAKER'S COD LIVER OIL AND Malt.

A combination of equal parts of these two potent remedies in which the taste of oil is completely masked and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

JOHN C. BAKER & CO.,

815 Filbert Street, Philadelphia.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

FOR THE INSANE.

CINCINNATI SANITARIUM.

Private Hospital and Residence.

(Incorporated 1873.)

Proprietary Interest Strictly Unprofessional.

Both sexes and all classes of mental and nervous diseases provided for.

Forty minutes by rail from C. H. & D. depot, Cincinnati. Address,

ORPHEUS EVERTS, M.D., Sup't.

COLLEGE HILL, OHIO.

THE RELATION OF SOCIAL LIFE TO SURGICAL DISEASE.[1]

BY D. HAYES AGNEW, M.D.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF PENNSYLVANIA; PRESIDENT OF THE AMERICAN SURGICAL ASSOCIATION.

Fellows of the American Surgical Association: As the generations fare on, enriched by the results of scientific labor, which pours its tides of opulence into all departments of human thought and industry, there follow, through a reactive or reflex influence, certain notable changes, not only in the life and manners of a people, but also in their physical and mental diseases. The more advanced a civilization, the more complex become the problems which surround it. While the accumulation of wealth and the multiplication of appliances for human comfort have, in the aggregate, contributed to the well-being of the race, yet there is reason to fear that the insatiate and ambitious demands of the masterful leaders in the work of the world, unless conditioned and environed by reasonable safeguards, may acquire their triumphs at the expense of human life. It is a suggestive and a solemn thought, that, in the victorious march of civilization, thousands of victims must perish beneath her chariot-wheels. There really seems to be a perpetual antagonism between man's inventions and discoveries and the well-being of a no inconsiderable fraction of humanity. He reduces the elastic vapor of water to practical use, and is rewarded by seeing countless numbers of human beings blown into shapeless masses by his rebellious servant. His chemistry creates formidable explosives, capable of dislodging the solid strata of the earth, and yet, in wicked hands, they become instruments for consummating such diabolical plots as serve to unsettle the peace of a nation! He rears manufactories for fashioning multitudinous fabrics which minister to the comfort and luxury of the race, and yet, while the hands of the fabricator are busy manipulating the materials of these industries, he is breathing a death-laden air. We send our missionaries to China and the Sandwich Islands to reclaim their peoples from the barbarities of heathenism, and then our commerce to ruin their souls and wreck their bodies. There seems, indeed, to be an eternal conflict between good and evil.

Considerations like these naturally lead to a very inviting field of study, namely, the relation between the material prosperity of a people and the forms of their disease. What I propose, however, in discharging one of the duties belonging to the honorable office to which by your kind suffrages I have been elected, is very briefly to follow one line of this inquiry, that is, The Relation of Social Life to Surgical Disease.

There is no tyranny more exacting or despotic than that exercised by the conventionalities which govern our living. All stages of life, from infancy to old age, are under its domination. It dictates the education, the manners, the walk, the dress, the forms of speech—in fine, the whole being. Beyond all contradiction, the behests of fashion are vastly more influential in governing public conduct than any arguments drawn from the teachings of structure

[1] President's Address before the American Surgical Association, September 18, 1888.

and function. As a rule, when the conflict is between taste and reason, the victory will be on the side of taste. In nothing is this more forcibly displayed than in the apparel used to protect the body. It is not an agreeable task to peer into the wardrobes or dressing-rooms of our fair countrywomen. I have no special taste for exploring museums of bizarre collections. Indeed, without a key to interpret the curious and ingenious mechanisms for clothing the form divine, such an exploration would be like an archæologist attempting Egyptology ignorant of cuneiform inscriptions. I have, however, some knowledge of human anatomy, in its broadest sense, and, when I look upon the masterpieces of the human form, whether in marble or on canvas—a Belvedere Apollo or a Venus de Medici—and contrast these with the dressed-out specimens of modern women, I am forced to admiration: not so much at the amazing ingenuity displayed in concealing the divinely-appointed form as at the plasticity and patient submission of mortal clay under the despotism of a conventional Inquisition. Were these processes of mutilation and abnormality harmless—did the body consist of a mere mass of protoplasm, capable, under the application of certain stimuli, of assuming normally Protean shapes, the subject might be passed over with the feelings of a naturalist; but this is not so. These violations of the laws of structure bring with them serious penal inflictions, which, did they terminate with the original offender, might be dismissed with a sentiment of pity; but, projecting as they do their baneful consequences to successors, they become proper subjects for criticism.

Let me name a few examples as illustrative of my subject. For some time, the profession has been speculating on the causation of nasal and post-nasal catarrh, with its accompanying auditory defects, the growing frequency of which cannot have escaped general observation. Doubtless no single agency will explain the presence among us of this unpleasant disease, yet there are facts connected with this affection which, to me, are very suggestive. I cannot recall an instance in which I have met with the disease among females belonging to the Society of Friends, Dunkards, or Mennonites. If this, on more extended observation, proves to be true, may not the head-dress peculiar to these people be accepted in explanation of their exemption? The bonnet, which at one time overshadowed the entire head, as all know, has been gradually shrinking in its dimensions, until it has become a mere shadow of its former self and offers no protection whatever to the head. As a substitute, I would not insist upon the quaint headgear of the Friend, though I believe that any modification which will protect this part of the body will lessen the tendency to catarrhal inflammation of the naso-pharyngeal mucous membrane.

Muscular Restraint.—A legion of physical imperfections arises from muscular restraint. Among these may be mentioned weak ankles, narrow or contracted chests, round shoulders, projecting scapulæ, and lateral curvatures of the spine. The foolish concession to appearance, and the unwise partiality of parents for enforced systems of education, the demands of which bear no just proportion to the capacity of the infantile mind, constitute the initial or determining force of these physical imperfections. In many cases, the weak ankles of children, characterized by eversion of the feet, thus allowing the superincumbent weight of the body to be transmitted to the latter inside of the proper centre of support, is largely chargeable to the miserable practice of placing on the little ones, long before they are able to walk, boots tightly laced up the limb some distance above the ankles. The confinement of the flexor and extensor muscles by this constriction prevents that free play of movement which reacts so favorably on all the elements of an articulation, and that, too, at a time when the growing forces are at full tide; so that, when the time arrives for standing and walking, the muscles are unequal to the firm support of the joint. The consequence of this feebleness is soon seen in the turning outward of the feet, throwing the strain on the internal lateral ligaments, which in turn become elongated through growth, and thus the defect becomes established. But the evil does not terminate here. The calcaneo-cuboid and the astragalo-scaphoid ligaments, losing the proper support of the tendon of the posterior tibial muscle under the abnormal tension, begin to yield, and to the deformity of eversion is added that of "flat-foot." That the above is not a mere hypothetical explanation of the ankle defects, I have many times verified by finding the threatening symptoms disappear after liberating the imprisoned muscles and subjecting the enfeebled parts to a judicious massage. Under no circumstances, as is too often the case, should instrumental apparatus be applied, unless in cases where, from neglect, the deformity is thoroughly established and is progressive.

Take another deformity—that of bow leg. On the earliest signs of the unsightly curve, the limb is too often trammeled with irons and the growth of the muscles arrested, when it is well known that, if manual force is systematically applied two or three times a day, the limbs will gradually assume their typical form.

Again, in further illustration of our general text, take, as an example, a child who, for one long or two short sessions, for six days of the week, sits over the study-desk, compelled to assume a position in which, from the inclination of the body, the shoulders fall forward, the head being supported, most probably, on the elbows and hands. In such a posture, the great serrati and pectoralis major and minor muscles are in a state of relaxation, while the erector spinæ and trapezii muscles are in a state of tension. This change in the position of the shoulders gives the scapulæ over, without antagonism or resistance, to the action of the rhomboidei and the levatores angulæ scapulæ muscles, which, acting conjointly, cause that projection of the lower angles of the shoulder-blades which the older anatomists termed "scapulæ alatæ." To all this must be added the very important factor of four to six hours in the schoolroom, and two hours, at least, of home preparation for the following day's recitations, during which time the respiratory function, having been reduced to a minimum of activity, the muscles of the chest are comparatively passive and æration of the blood tardy. Certainly no combination of conditions could be better devised for forming contracted chests and round shoulders. It is not long before the watchful eye of the mother detects the change in the lean figure of her child. She will probably discover this and take alarm, even when the pale face, the languid air, and the capricious appetite of the child cause no anxiety; and then comes the second act in the drama of physical deterioration, namely, a resort to shoulder braces and stays, in order to accomplish that which the muscles should be taught to do without restraint or incumbrance.

Lateral Curvatures.—While it is true that lateral curvatures of the spine depend upon causes both central and peripheral, yet in no small number the deformity is clearly attributable to influences of a social nature. The young column, by reason of the non-union of the epiphyses and diaphyses and the supple character of its ligaments, is extremely flexible. Whatever, therefore, destroys the muscular equipose, however inconsiderable the force, if persistently repeated, changes the centre of gravity and develops primary and compensating curves. For six months in the year, any fine morning, groups of young children may be seen plodding along our streets with a miniature library of books suspended from one shoulder. To the already preponderating scale of the balance add the additional factor, a probably badly arranged light, compelling these little *savants* to assume a lateral inclination of the body in order to obtain the necessary illumination of the subjects of the study, and you have all of the conditions necessary for perpetuating the lateral deformity. "Just as the twig is bent, the tree's inclined." As in the case of round shoulders, so here, in order to prop up the falling column, instrumental contrivances are immediately called into requisition. The body is encased in a formidable coat of mail, to be followed by muscular atrophy and permanent distortion of one of the otherwise most beautiful pieces of mechanism in the human frame. It is true that, in most educational institutions for the young, provisions are made for physical culture, and these are in some measure antidotal to the evils complained of; but in my judgment they do not at all compensate for that free unstudied romp in the open air, untrammeled by the hard and fast rules of calisthenics, so fascinating to the young child. Nor does the evil end here. While the forcing process, which is to stimulate the mental powers far beyond the real capacity of the immature and growing brain to receive, is in progress, another is inaugurated, which is to qualify, especially the female child, to acquit herself with distinction when the time arrives for entering the great world of society, or, as Thomas Browne would style it, "for the frivolous work of polished idleness." The gait and carriage must be reduced to prescribed rules, the voice toned down to a drawl or trained to move like a mountain torrent. The muscular apparatus of the face must be taught to express, not the spontaneous and natural outflow of feeling which wells up unbidden from the magic chamber of the heart, but rather to produce an effect; and so this work of transformation goes on until it culminates in the full-blown society girl. Is it any wonder that under such a scheme of education, conducted throughout by a studied disregard of both the physical and mental constitution, and exercising as it does such tremendous drafts on the nervous system, the world

is becoming filled with a class of flat-breasted, spindle-limbed young women, unfitted for the varied and responsible functions of womanhood — qualifications, too, which, under a different regimen and directed into proper channels, would exert a most potential influence on all the great social and moral problems of the age?

While thus plain-spoken on the frivolous methods of living, I do not wish to be understood as being unfriendly to the highest cultivation of the mental and physical powers, if conducted on lines in harmony with the organization, nor to any technique which may conduce to personal grace or elegance of manners, so that the manly or womanly personality of the individual be not sacrificed to the Moloch of sentiment and sham. Indeed, indifference to these things is inexcusable in either man or woman as not only lessening their influence in the world, but in many respects disqualifying them for the highest discharge of the duties of modern life. Valuable as may be the unpolished diamond, yet it is only after the wheel of the lapidary has worn away the dull incrustations that its true brilliancy is revealed and the gem is fitted to adorn the brow or the breast of beauty.

Bodily Constriction.—In the further discussion of my subject, I may next notice the evils of visceral displacement and pressure, consequent on abdominal constriction. Whatever may be said in regard to Greek and Roman life, the infinite care which these people displayed in developing and maintaining the very best type of the human form is worthy of admiration. The Ionic "cheton" spoken of by Attic writers and so often represented in the bronzes of Herculaneum, while it would not exactly satisfy the modern idea of dress, was at least free from the charge of interfering with the contour of the human figure. The painters and sculptors of those classic days were reverent students of nature. Their delineations were true to life. Their works furnish us with no hour-glass contractions of the human body. The constriction of the waist operates injuriously on both the supra- and infra-diaphragmatic organs. Any force acting on the base of the thorax and preventing the expansion of its walls concentrates the function of respiration, which should be general, on the apices of the lungs, and hence, under these circumstances, the movements of breathing are for the most part confined to the summit of the chest. As the initial seat of tuberculosis is located at the upper part of the lungs, may not the inordinate work entailed on these parts by constriction have some part in hastening such deposits in the female where the predisposition exists? It is this forcing inward of the costal border of the thorax which causes the groove on the anterior surface of the liver, so familiar to anatomists. This pressure cannot fail to interfere with the descent of the diaphragm and with the functions of the gall-bladder and duodenum, and exercises no small degree of influence in favoring the formation of biliary calculi, females being peculiarly prone to such concretions. The extent to which the liver may be damaged by extreme constriction of the waist is well illustrated by a case quite recently reported in the *British Medical Journal*, in which a considerable portion of the left lobe of the liver had been separated from the right, the two being connected only by a band of connective tissue, thus enabling the operator to remove the detached mass without difficulty. The evil effect of this constriction on the viscera of the abdomen and pelvis is most strikingly witnessed in the embarrassed portal circulation, in the different uterine displacements, elongation of ligaments, displaced ovaries, tubal inflammations, hemorrhoids, hernia, and other morbid conditions which either prevent or disqualify the woman for the exercises of the functions of maternity; and which in addition, through reflex influences, entail a host of functional disorders reaching into every avenue of the body and invading both the mental and moral constitution of the victim. So prolific have these infirmities become that a new department of surgery has been organized for their special management. To what, if not to social causes, can these morbid changes of structure in the pelvic organs, especially of the uterus and its appendages, be attributed? Why should laceration of the cervix uteri be so common an accident? Labor is a natural process, and should not under ordinary circumstances be attended by lesion of uterine tissue. I can conceive of no agency more likely to induce that muscular degeneration which predisposes to this accident than the modes and methods of modern living, especially among the inhabitants of great cities. In the expression "modern living," much is embraced. It includes culinary pharmacy, over feeding and drinking, insufficient or injudicious exercise, improperly heated apartments, and a disproportion between the hours of exercise and rest. Contrast, if you will, the muscles of the hardy country housewife, who,

bearing the cares and responsibilities of a dependent family, bustles about the live-long day indoors and out-of-doors, eats with a relish her plain and simple fare, repairs at seasonable hours to bed, and sleeps the sleep of the beloved, undisturbed by dyspeptic nightmares, and, rising with the golden dawn, resumes the round of domestic toil with a clear head and supple limbs—I say, contrast this type of a class with that of another, the woman born to luxury and ease, whose capricious and exacting taste taxes the art of the professional caterer, who drags out the morning hours toying with some crazy piece of embroidery or trashy novel, lunches at one, rides out in the afternoon for an airing of two or three hours, returns to a dinner of five or six courses at seven, completes the evening at the opera, the theatre, or the assembly, and, coming home after midnight, crawls into bed weary and exhausted in body and mind, only to rise, with the best hours of the morning gone, for another day of aimless routine life. Can it be doubted that, in the first case, with a digestion unimpaired, with the products of textural change consumed by functional activity and eliminated through the proper emunctories, the woman should possess a vital resistance and a tone of tissue altogether superior to that of the other, whose habits of living must necessarily favor their faulty metamorphosis?

To these same agencies must be attributed that brood of nervous and hysterical evils, for the relief of which the gynæcologist, too often I fear, invades the domain of womanhood, around which her whole sexual nature revolves, and which, save only in the direst extremity, should be sacred against all operative intrusion.

Late marriages constitute another social evil, the penal inflictions of which involve both sexes alike. Pride and luxury determine long engagements or defer proposals. Marriage, it is believed, necessarily involves an establishment, a display, a retinue of servitors. The good old notion of two souls being united in wedlock for the purpose of being mutual helpmates, and patiently together working up from modest beginnings to affluence, seems to be entirely at variance with the modern idea of this relation. In the meantime, the young man is betrayed into unlawful sources of gratification, alike destructive to moral and physical purity, the pollution of which by incontinence is often subsequently communicated and perpetuated to wife and offspring. I would not dare to say how many cases of this nature have been entrusted to my professional confidence, though I doubt not my experience does not differ from that of many of my professional brethren whom I address. It is under such circumstances that many of those infective inflammations of the Fallopian tubes, such as salpingitis and pyo-salpinx, arise, which entail the most serious deterioration of health.

The Foot and the Shoe.—It may be thought by some persons that the subject of the foot and the shoe is not of sufficient dignity to appear in a public address. The Romans and the Greeks thought differently. The literature of both peoples is full of references to the shoe worn by both sexes. So important indeed are the feet to the well-being of the body, that whatever impairs their usefulness, either for support or locomotion, becomes a positive calamity. Nothing can be more unlike the human foot than the modern shoe. Let anyone leave the impress of his or her foot in the wet sand of the seashore, and then place alongside of the imprint a fashionable shoe; that the two were ever intended for each other would scarcely strike a child of the forests. The North American Indian entertains juster notions about clothing this portion of his body than does the civilized denizen of New York or Philadelphia. Compare the moccasin with the shoe of the city belle. Compare the σανδάλιον or the περσικαί of Pollux and of Aristophanes with the same, and we shall see that the savage and the polished Greek alike understood the value of sound feet in the race of life. It is the imperfect adaptation of the shoe to the foot, which constitutes the fruitful source of tired ankles, corns, bunions, over-lapping of the toes, and ingrowing nail. Some idea may be formed of the magnitude of the evil from the fact that, of eight hundred patients under the care of a prominent chiropodist of Philadelphia, the great majority of the defects were entirely attributable to the high heels and the contracted toes of the shoes. Especially do these physical incumbrances arising from a blind submission to social laws operate disadvantageously to our fair women at the beginning of the new dispensation requiring both muscles and brains, and when her friends propose to sweep away all the old traditions and claim for her the earth with all its masculine employments.

Games and amusements, which in themselves are proper and praiseworthy, too often become developed into a craze, working both moral and physical mischief.

Professor Leuf, himself a professional in the national game of base-ball, has described the pitcher's arm, a condition of over-taxed function, and one in which all the anatomical elements of the upper arm are involved. There are also the tennis arm and the swollen supersensitive prostate of the bicyclist, both due to the abuse of popular amusements.

Defects of refraction or visual defects constitute another class of affections fairly attributable in many instances to social influences. The number of children who may be seen in our streets any day, wearing glasses, has become a matter of common observation. It is far from being probable that the most exquisite piece of mechanism, the human eye, came from the Divine Artificer imperfect. Because eyes are young, it does not follow that they are thereby better fitted to sustain prolonged use. Just the reverse is true, and it is high time that parents and educators should begin to recognize the fact. The power of the eyes for continued use, like that of other organs of the body, is one of gradation. It moves in the general procession and strengthens with the advance in life until development has attained to its zenith. Not only so, but the eye, being a part of the body, must suffer or rejoice through the operation of general causes. A bone may have its normal curves changed, a tendon may slip from its appointed groove, or a blood-vessel be destroyed, and yet very little disability be realized; but the eye is made up of such extremely delicate structures and acts according to fixed physical laws, so that not the slightest alteration of a curve or the mobility or density of its media can occur without great vitiation of function. To exact, therefore, long hours of study from children of a tender age involves a degree of functional strain altogether disproportionate to the structural resources of the organ, and, by disturbing the orderly processes of nutrition, gives rise to hypermetropia, asthenopia, astigmatism, and its companion, headache. That the picture is not too highly colored, or the causation overstrained, we have only to contrast the children born and reared in those portions of the country not too much dominated by the methods of modern civilization, and who rarely demand a resort to artificial aids to provide for abnormalities of vision. The only remedy for the evil, where infantile scholarship is insisted upon, is the kindergarten, or object system, the most natural and effective plan of impressing the young mind.

Renal Disease.—Is there any reasonable explanation drawn from sources of a social nature for the great frequency of those renal disorders which come more especially under the care of the surgeon, such as crystalline deposits and calculi? For maintaining the general health at the highest physiological standard, a proper quality of food and the proper disposal of tissue-waste are essential conditions. Along with wealth and luxury come the abuses of the table. Americans are fast becoming a nation of dyspeptics. Our country is so rich in the products of every zone that nowhere else in the world can be found such a variety of foods, animal and vegetable. These foods, manipulated in a thousand ways by the subtle art of the professional cook, almost necessarily betray one into excess, and also create the desire for wines and other alcoholic beverages to aid the stomach in disposing of its plethoric supply. In great cities, which furnish relatively the largest number of cases of renal disease, affecting pre-eminently the mercantile and sedentary classes, we find just the conditions favorable to their development. The competitions of trade keep the merchant always at white heat. Time is golden, and the street-car and other means of conveyance annihilate distance, and the ride is substituted for the needful walk. A hasty lunch at the most convenient restaurant satisfies the inner man until the business of the day is closed, when, weary and worn, he is driven to his home to partake of a course dinner, the balance of the evening to be spent on the lounge with the evening paper or the latest periodical. The fascinations of the study and the library charm the literary man, with their siren voices, away from the fields and the highways until bodily exercise grows distasteful and repugnant. In the meantime there has been no provision made for the waste or tissue metamorphoses of the body through that great agency, exercise. These waste products accumulate in the blood, the internal eliminating organs, of which the kidneys are chief, are overtaxed, and then follow the evils of malassimilation and of excretion in the form of urates and oxalates, often resulting in the formation of calculi.

In conclusion, may we ever hope for a time when the race will realize that these bodies which we wear, which God has so highly honored by his own incarnation, are sacred temples to be kept in harmony with recognized physical laws, and not to be made instruments of mere animal gratification!

THE HYPODERMIC USE OF MURIATE OF COCAINE IN ORAL SURGERY.

BY ARTHUR C. HUGENSCHMIDT, M.D.
(UNIV. PA.), PARIS, FRANCE.

In this communication, cocaine shall be considered as used hypodermically only, as my intention is not to make a revision of the different ways in which muriate of cocaine is or has been used.

Cocaine hypodermically has been used for some time by many practitioners; I must state, however, that my attention was called to the fact of using this method in oral surgery while listening to the excellent lectures delivered by Prof. Horatio C. Wood at the University of Pennsylvania in the early part of 1885, when he recommended the hypodermic use of this drug to produce local anæsthesia in cases of minor surgery, opening abscesses, felons, etc. Some months later, having a portion of necrosed bone to remove from the outer alveolar portion of the superior maxillary bone, cocaine was injected and the operation performed painlessly.

I have, up to date, administered this drug in this way in over 400 cases, and have had five cases in which severe symptoms have presented themselves, which were due to the physiological action of the drug. In from 15 to 20 cases, I have noticed one or more of the symptoms presented by the first series; all the others felt perfectly well; I have had only one local accident.

I prepare my hypodermic solution myself, as it is quite important that it should be perfectly fresh. To do this, I prepare little packages containing each one grain of muriate of cocaine; when I want to make my solution, with the hypodermic syringe twenty minims of distilled water are measured in a teaspoon, the cocaine salt (1 grain) is then added; ten minims of this solution, or ½ grain, is the quantity required. This dose will, in certain persons, produce quite severe symptoms; hence I do not think it advisable to recommend one grain.

For any operation on the mouth, removal of small tumors, of necrosed bone, of roots or teeth, make a double injection of five minims each of the above solution on each side of the operation-field; for the removal of a root, for instance, make an injection on the outside of the alveolar portion, and one on the inside, in the palatal region, opposite the root to be removed. In five minutes, even less, you can excise your tumor, remove the diseased bone, or extract a root, painlessly.

I must also recommend especially that, whenever we are in the neighborhood of a bone, we must be careful that the injection is not made while the needle is in contact with the bone, or else a detachment of the periosteum will be produced, which would bring on a local slough and necrosis; this has occurred to me in one case only, but it is enough to enable me to guard others against such an annoyance.

Another precaution not to be forgotten is to wash the operation-field, before inserting the needle, with an antiseptic solution, bichloride (1–1000) being one of the surest; this precaution is especially necessary when we operate in the mouth.

Let us first consider the local action of the drug. The anæsthetic action (local, of course) is an almost immediate one in certain cases; in others, it will take from two to five or seven minutes. At the time of injecting, the parts which surround the point of injection become temporarily bleached—due, of course, to the force necessary to introduce the liquid in such dense tissue as the gums. The local action of the drug is a twofold one: its immediate effect is an anæmia of the injected part, due probably to a stimulant action on the vaso-constrictor of the peripheral vessels; the local anæsthetic effect is due to an inhibitory action on the peripheral sensitive nerves. These are the results obtained by Laffont and Arloing; in fact, Laffont calls cocaine "sensitive curare," its action, according to him, being to act on the termination of the sensitive nerves as curare does on the peripheral motor nerves. Brown-Séquard has drawn attention to the fact that sensibility to pain alone disappears while the tactile sensation remains, with all agents which act on the peripheral nervous system. This is the case with cocaine, for I have always noticed, whenever I have given the drug in injections, that after the operation the patient will report that he has felt nearly every step of the operation, without any pain whatever. Cocaine is then a local anæsthetic to pain only, and not to tactile impressions; it is then a true local anæsthetic. Brown-Séquard has also demonstrated lately that, when cocaine is injected directly into a vein, a general anæsthesia, similar to that of chloroform or ether, will be produced—an insensibility to both painful and tactile impressions.

Passing now to the consideration of the

action of cocaine on the general system, we find that, when ½ grain of muriate of cocaine is injected, in the very great majority of cases no unpleasant symptoms will present themselves, provided that the patient is in a normal state, not fearing the approaching operation. If, however, a person presents himself, frightened at the coming operation, we must be extremely careful, and I should even advise never to inject cocaine in a person who shows the least fear. Try to convince him of the simplicity and painlessness of the operation; if you do not succeed, postpone your operation to another day. If you do inject when the patient is in that state of fear, you will certainly produce a *partial unconsciousness*, which is a peculiarity of the action of cocaine, for I have never seen complete unconsciousness in all my practice with the drug.

The symptoms produced in frightened persons or those especially susceptible to the action of cocaine, given in doses of ½ to 1 grain, are the following: From thirty seconds to two minutes after the injection, the patient complains of a strange feeling in his head, a sense of emptiness; he then becomes pale, and, with the increase of the pallor, he complains of cold all over; in one case, formication in the extremities was experienced. Respiration soon becomes slowed, irregular, embarrassed—a gasping respiration. The pulse runs up to 110 or 130. The patient never loses consciousness. He is in a state of partial insensibility; he remains perfectly quiet, eyes closed, this state of quietude being every now and then broken by a gasping inspiration. This state very much resembles the later stages of opium-poisoning; the patient will open his eyes, if you tell him to do so; he will answer your questions, but will immediately sink into his former condition. If you ask him if he feels bad, he will invariably reply that it is a most delightful state to be in, and two of my patients told me they regretted that this state did not last longer. On the contrary, when the drug begins to act and the patient feels faint, two or three of my patients have told me they felt as if they were dying. This only partial insensibility seems to be corroborated by Dr. Djerine's case, in which the patient himself had taken 15 grains of cocaine muriate; he remained apparently unconscious for half an hour, but afterward assured the physician that he felt him when he pinched his hands. Consciousness is, therefore, not entirely lost to the patient, although it seems to be to those who surround him. The pallor of the face and the sensation of extreme coldness in the extremities indicate certainly a general vaso-motor disturbance. Cocaine seems also to influence very much the circulation, as well as the respiration, which it probably effects by a great disturbance of the cerebral circulation at the base of the brain, resulting in cerebral anæmia. Laffont has indicated that it had a very exciting action on the vaso-constrictor filaments of the great sympathetic nervous system.

How can we explain the apparently increased physiological action of the drug on frightened persons? We must first consider the state of the cerebral circulation in such persons. Surgeons and physiologists who have the opportunity of seeing the brain exposed, either after an accident or artificially so in animals, tell us that if such a man, whose brain is exposed, becomes frightened or is wrongly accused of having done a certain act, his face becomes pale, and at the same time there is a depression of the surface of the brain, which, in addition, loses its normal slightly pink color and becomes anæmic. Now, the same occurs in any patient about to be operated on, who is at all frightened. If to such a patient, whose brain is already in a state of anæmia, you administer cocaine, which also renders the brain anæmic, a series of symptoms indicative of brain-anæmia will certainly follow. Such symptoms are: A tendency to unconsciousness, pallor of face, coldness of the surface of the body, etc.

On the other hand, the condition of a person who has been tickled for some time, or who has laughed a great deal, is exactly the reverse from the frightened persons; the cerebral circulation, instead of becoming anæmic as in fear, is, on the contrary, increased; there is a temporary congestion. If to such a person cocaine is administered, this drug will counteract the action of the tickling on the cerebral circulation, and no symptoms whatever should be noticed. The following case illustrates this statement. To a young person, 25 years old, I had to administer cocaine for a certain operation; ½ grain produced the above-described alarming symptoms. About one month later, having another operation to perform, I talked to the patient a long time, and tried to induce him to laugh; when this patient's face was congested, I suddenly introduced the needle and injected ½ grain as before; no symptoms whatever showed themselves. I have also given cocaine to plethoric subjects with very much congested faces, even up to ¾ of a grain and 1 grain, without producing

the slightest symptom, although in two cases the patients were quite frightened.

The influence of fright and the previous knowledge of the symptoms produced by cocaine are well exemplified by the following case. A woman about 60 years old, desiring to have a tooth extracted, I was called to administer the cocaine. I found the patient in a highly nervous state; she said that she knew cocaine produced bad symptoms—a terrible sensation in the head and fainting. I at first refused to administer the drug; but, as she insisted, I finally consented, but gave her instead ten *minims of distilled water;* in less than half a minute she complained of a terrible sensation in her head, and soon *fainted completely*, but not in the semi-unconscious state characteristic of the effect of cocaine, as her physician had forgotten to specify to her this particularity. This was, of course, an instance of auto-suggestion or self-hypnotization.

Care must be exercised in administering cocaine to anæmic patients. Two of my general accidents occurred in anæmic patients. One of them is interesting on account of the influence of an iron treatment on a subsequent operation. Having given as usual ½ grain of cocaine muriate, the patient had the symptoms described above; after having placed her on an iron treatment for six weeks, when she returned I renewed my cocaine injections; no symptoms at all presented themselves; she felt perfectly well. Hysterical patients are also to be carefully managed, as I produced in my earlier use of the drug a fit of hysteria—by the use, it is true, of a large dose (about one grain of cocaine).

As cocaine seems to have such a decided action in rapidly lessening the cerebral circulation, should it not be advisable to try its use hypodermically in cases of cerebral hemorrhage or apoplexy, or even in sunstrokes? About a month ago, a woman came to me, and while in my office she was suddenly seized by palpitation of the heart, suffocation, and her face became congested; it was a very warm and close day. I then thought of using cocaine, and injected 7 minims of my solution (about ⅓ grain of cocaine); in less than two minutes she told me she felt perfectly well again, and had begun to feel better a few seconds after the injection was made.

As to the treatment of the bad symptoms produced by cocaine. If there is only a slight fainting, the use of the ordinary smelling-salts will be all that is required. If, however, the patient remains pale, pulse rapid, respiration embarrassed, drowsy, give him occasionally, to inhale, about five drops of nitrite of amyl, placed on a handkerchief, and ward off sleep by talking to him continuously and moving his arms up and down.

In one of my anæmic patients, in addition to the above, I gave, with excellent results, a hot brandy punch, in which were forty drops of ether. Finally, in cases of very severe symptoms, when a person has taken several grains of cocaine, the repeated hypodermic injection of ether will certainly prove to be of the greatest use.

AN ALMOST UNRECOGNIZED CAUSE OF DISEASE IN YOUNG CHILDREN.

BY HIRAM CORSON, M.D.,
CONSHOHOCKEN, PA.

During my many years of practice, there have been many occasions on which I found it necessary to warn persons who used tobacco against using it in the sick-room, especially in the lying-in room. I have often known poor men, after coming from work and also in the early morning, to fill the room where there was an infant only a few days old, with tobacco-smoke, and that some of these children sickened and died from the effects of it I have no doubt. Three years ago, I was passing along Green Lane, a street running from Roxborough to Manayunk, when I met a young man proudly carrying a child of but a few months, on his shoulder, with the child's face close to his own head. He was smoking, and, as he faced the wind, the smoke was carried back into the child's face. It was Sunday, and himself and wife had apparently just started to visit friends in Manayunk—a very short distance. After I had gotten away from them, I reproached myself for not having accosted them and warned them of the child's danger. It is quite probable that, before they reached their friends, the child was sick; then, if a doctor was sent for, he was doubtless told: "It was quite well when we left home, and we can't tell whatever has made it so sick." Being so very sick, and malaria being so plentiful in that region, the doctor could readily see that it ought to have medicine—some antiseptic or some germicide—and then—well, we may fancy the rest.

I have often, when called to young children, believed that the cause of the sickness

was due to the fumes of tobacco; removing them from the cause often soon placed them in safety. And yet that many suffered from that cause, and that it was not recognized as such by me, I have no doubt.

Can it be possible that an infant could be subjected to so potent a cause of disease without being deeply affected by it? But it would be difficult for the most vigilant physician, however anxious to prove this a frequent cause of sickness, to do so. Children, no doubt, often become accustomed gradually to the fumes of tobacco, and after a while they have little effect on them. But that it has a deleterious effect on children of even one or more years of age is probably true.

In *Friends' Intelligencer and Journal* of the present month, there is reported a case so carefully observed and so evidently caused by tobacco, that I feel it to be important to give it to your readers. It is entitled:

"Important to Fathers who Smoke."

"May I give you my recent experience of tobacco-smoke? It may be a warning to others. I have one child, a little girl not yet two years old, who was as healthy as the birds when she was born. For more than a year past, ever since she was old enough to be less in the nursery and more with her father and me, she has ailed mysteriously. I could not say she was ill, yet she was hardly ever well. I was in a perpetual state of anxiety about her. The symptoms were absence of appetite, complaints of sickness, stomach and digestion out of order. Last August, I took her to a country town, where we stayed two months. After the first week, she flourished like a young bay-tree, ate, and drank, and laughed, and played, and slept, and kept me forever busy enlarging her garments. I brought her home rosy and robust. In one week, all the old symptoms reappeared—loss of appetite, dark lines under the eyes, listless ways, restless nights. Some one suggested that the neighborhood did not suit her; and I was cogitating how to take her away again, when she caught a severe cold and was confined entirely to one room for three weeks. She recovered her health completely. Appetite, spirits, sleep, all returned. It could not be the neighborhood. After her cold, she joined us downstairs again, as usual, two or three times a day. In less than a week, sickness, etc., returned. I was in despair. For nearly three months, I racked my brains about drains, wall-papers, milk, water, sauce-pans, any and every thing in vain—the child slowly wasted. The weather was too severe to take her away. In an agony of mind, I noticed one day that, so far from out-growing her clothes, as I expected, they were too large for her. The little thing was not eating enough to keep up her strength, and we could not coax her to eat. Yet she was not really ill; she ran about and played in a quiet way, and looked fairly well to those who had not seen her more robust. Suddenly my husband was summoned into the country. A week after he went, she began to eat with a relish. In a fortnight, she was her own happy self, full of riotous childish spirits. 'Her father has never seen her like this,' I remarked, one evening, when she was particularly merry and mad; and then the truth flashed upon me. It was his tobacco that upset her. He has been away now for a month; and the child's limbs daily get firmer and rounder, and she is the merriest, healthiest little mortal possible. He always smoked after breakfast and after lunch, with her in the room, neither of us dreaming that it was injurious to her. But for his providential absence this time, it would never have occurred to me, and we might have lost our darling, for she was wasting sadly. It was acting like a slow poison."

It seems to me probable, from the above history, that the child was confined to the nursery for the first few months, and not with the father when he was smoking, and was thus not affected so early as children often are. With rich people, in cities, the "smoking-room" saves children, infants at least, from early poisoning by tobacco-smoke. But that thousands of infants, in the homes of the poor in the small crowded houses of the alleys in cities, are sufferers from this cause is quite probable. People with consumption and other exhausting diseases are sometimes greatly nauseated by the odor of tobacco brought into the sick-room by a physician much given to the use of tobacco. I have several times heard them speak of its being very offensive to them.

As "a word to the wise is sufficient," it seems to me quite proper to call the attention of the profession to this cause of disease, of suffering, and ofttimes of premature death.

—The New York State Medical Association will hold its fifth annual meeting at the Hotel Brunswick, Fifth Avenue and Twenty-seventh Street, New York City, October 9, 10, and 11, 1888.

CASE OF TRAUMATIC TETANUS; DEATH.

BY LLEWELLYN ELIOT, M.D.,
WASHINGTON, D. C.

Charles McG—, white, aged 9 years, on March 16, ran a splinter, one inch long, into the thumb of the right hand; a portion of it was removed at the time. Four days later, the thumb began to swell and to become painful. Poultices of flax-seed meal were applied. On the ninth day after the injury, the remaining portion of the splinter was removed. On March 26, he complained of stiffness of the jaws, general malaise, pain about the chest, and by night of the same day the jaws were locked. On March 27, the following prescription was ordered for him:

℞ Chloral. hydrat. . . . . ℥ iij
Potass. bromid. . . . . ℥ iij
Aquæ font. . . . . f℥ ij
M. Sig. A teaspoonful every half-hour.

During the day, he had two spasms. At eight o'clock in the evening, he was sleeping, but was very restless. The medicine was then ordered to be given every hour. On March 28, he had two spasms toward morning; they did not last more than a minute. The following was ordered in conjunction with the chloral mixture:

℞ Tinct. cannabis indicæ . . . . . f℥ i
Sig. Fifteen drops every two hours.

At 11.15 A. M., his pulse was 135; he was awake; had had an attack marked by opisthotonos; the jaws were not so closely set as they had been the day before. At 1.45 P. M., he was given gr. ¼ morphia sulphate; this was repeated at 6 P. M. At 11.30 P. M., he had been sleeping much; the bowels were moved by an enema.

March 29, 2 A. M.: Bowels have moved again, pulse 174; suffers much from thirst; there is slight movement of the jaws. At 2.35 P.M., he had a convulsion, the first one since 11.15 yesterday morning. At 4 P. M., he had another convulsion, and at 5 P. M. he had another, during which he died.

Milk was the only nourishment he would take during the time of his illness, and the parents afterward admitted having stopped giving the medicines, because he did not want to take them. The improvement following the use of the remedies above mentioned would, I believe, have been permanent, had the parents persevered in their use, and I am encouraged to employ them again when another occasion presents itself.

ACETATE OF LEAD IN THE TREATMENT OF DIARRHŒA.

BY L. L. AMES, M.D.,
REYNOLDS, NEB.

I desire, in the short article which I herewith submit to the readers of the REPORTER, to give my experience with an old and valuable remedy, which, in the modern whirl of excitement after new remedies, seems to have been almost forgotten by the profession.

On July 27, 1888, I was called to see G. N., six months old, and I found my little patient could keep nothing on its stomach and showing indications of extreme thirst, while its bowels were moving every hour or two, the discharges being green and very watery, and the temperature in the axilla was 103½°.

I ordered the child to be sponged with tepid water to which a little bicarbonate of soda had been added. As the head was extremely hot, cloths wrung out of cold water were kept constantly applied to it, and I prescribed

℞ Tr. opii . . . . . gtt. xvi
Bismuth subnit. . . . . ℥ ii
Mist. cretæ . . . . . f℥ iss
Syr. simp. . . . . f℥ ss
M. Sig. A half-teaspoonful once in three hours.
(J. Lewis Smith's prescription.)

On the next day, I returned and found my patient in no way improved, excepting that it slept more and was more quiet. I continued the prescription. July 29, I found the child's temperature 102½°, its tongue dry and brown, accompanied by extreme thirst and frequent watery discharges from bowels. It could retain only a very small quantity of nourishment. I ordered barley-water to be given in place of water, for the thirst, and, as the child did not nurse, it was given small quantities of cow's milk once in two hours and a half, to which was added lime-water. Small powders of ingluvin were given after taking milk, and the prescription of July 27 was continued. July 30, there was no improvement; the child's extremities were cold; its axillary temperature was the same as before. I now ordered alcohol to be added to the baths, withdrew the bismuth prescription, and ordered one grain of salol to be given every two hours, and warm applications to be made to the extremities. July 31, there was still no improvement. August 1, I found the child very much emaciated; its eyes were rolled up in its head, the eyelids only

partially closed, and the conjunctivæ congested; the temperature was 102½°; the discharges from the bowels were about the same, and the abdomen was considerably distended with gas, while the other symptoms about same as before. I now ordered cloths wrung out of hot water to be applied to the abdomen, and the following prescription to be used:

℞ Plumbi acetat. . . . . gr. iss
Tr. opii . . . . . gtt. x
Spr. vini Gallici . . . . . f ℥ ii
Aquæ . . . . . q. s. ad f ℥ i
M. Sig. A teaspoonful once in three hours.

I also ordered small powders of pepsin and ingluvin to be given after each time the baby took its nourishment. August 2, I found the temperature 101°, the bowels free from gas, and that only four movements of the bowels had taken place since I last saw it, while all the symptoms showed improvement. The last prescription was now given only once in four hours, and a few drops of brandy were given between the doses, so that the infant got a little stimulant once in two hours. I also gave half a grain of quiniæ sulph. once in four hours. August 3, I found the child's temperature normal; that it had had only two discharges from the bowels in twenty-four hours; that its mouth and tongue were becoming moist, and that it was showing an inclination for food. I therefore discontinued the acetate of lead prescription, but continued the quinine and pepsin. On the next day, finding my patient still improving, I prescribed a tonic of cinchona and iron, to be continued for several days, and the child has now made a perfect recovery.

A second case in which I used the acetate of lead successfully in the treatment of diarrhœa was that of a woman in the third week of typhoid fever. She had lost control of the bowels entirely, the discharges being involuntary. I had used bismuth subnitrate, ten grains, with a grain of powdered opium, given every four or six hours, but it had failed to give relief. One-sixth grain of nitrate of silver was added to the other drugs without effect. Suppositories composed of ten grains of bismuth subnitrate, two grains of powdered opium, and one-fourth grain of nitrate of silver were equally useless. I then ordered

℞ Plumbi acetat. . . . . gr. ii
Tr. opii . . . . . f ℥ ss
Aquæ . . . . . f ℥ iss
M. Sig. A tablespoonful once in four hours.

The discharges immediately became less frequent, the soreness left the bowels, and, after the first dose of the prescription was taken, the gain was steady, until now convalescence is fully established.

In closing, I beg to say that I believe many young practitioners, and some old ones, fool away too much valuable time experimenting with every new medicine that is brought to their notice by advertisements, while they leave untried the old remedies which have stood the test of years.

Hospital Notes.

Philadelphia Hospital.

(Service of Dr. William Osler.)

Reported by F. W. Tally, M.D., Resident Physician.

Blue Spots in Typhoid Fever.

In connection with the note on Blue Spots, by Dr. Osler, Reporter, August 4, p. 156, the following case will be of interest:

Patrick O'B., 19 years old, was admitted to the medical wards of the Philadelphia Hospital, August 17, 1888, under the care of Dr. William Osler, suffering from typhoid fever, in the eighth day of the disease. On examination, several pale-blue spots were noticed on the abdomen, in the right lumbar and the epigastric regions. They measured from three to six lines in diameter, were irregular in outline, not elevated, and not disappearing on pressure. No red spots were seen, although carefully searched for. On the following day, three new spots appeared near the umbilicus. New spots were seen each day over the abdomen, a few being found in the right axilla and in the bend of the left elbow. Usually they began to fade on the fourth day, disappearing about the sixth. They reached their greatest number about the twentieth day of the disease, when three rose-red spots appeared on the abdomen, and by the twenty-fourth day only a group encircling the umbilicus could be found.

The temperature during the disease has been high and obstinate, although delirium has not been present. With reference to the French view, that these spots are produced by pediculi, it may be noted that the patient was most carefully watched, and no trace of lice detected.

—Dr. Stephen Smith writes to the *Medical Record* that several years ago he transplanted seventy-five particles of skin from a leg which had been amputated over two hours; seventy-three of the particles of skin lived and grew vigorously.

PERISCOPE.

Treatment of Epilepsy by Galvanization of the Thyroid Body.

Since the works of Kocher, Juillard, Schiff, and others, says the *Bulletin Médical*, August 22, 1888, we know that, in man and animals which have been subjected to total extirpation of the thyroid body, a cachectic state (*cachexia strumipriva*) develops, which is accompanied with trembling and attacks of tonic and clonic convulsions much resembling true epilepsy. These facts have induced M. Signicelli (*Revista clin. e ter.*) to think that some epileptic patients may present conditions more or less analogous to those of animals which have undergone thyroidectomy; that, in other words, there exist, perhaps, some forms of epilepsy produced by a functional alteration of the thyroid gland. This idea has been confirmed in a certain measure by the study of two patients in the insane asylum of Ferrare, in whom the correlation between the state of the thyroid body and the psycho-nervous functions was evident. The first, a maniac, presented a marked swelling of the thyroid body, which was tender even upon very slight pressure and during the movements incident to deglutition. The pupils were enormously dilated, and reacted but slowly to light. The swelling of the thyroid diminished until it disappeared completely in the course of twelve days. At the same time, the symptoms of psychic excitation diminished and disappeared, and so did the mydriasis. In the second patient, a young epileptic, the thyroid body, uniformly swollen, was the seat of spontaneous pain, recurring in paroxysms. However, M. Signicelli was unable to prove, in this case, any connection between the phenomena on the part of the thyroid gland and the epileptic paroxysms.

Signicelli then tried the effect upon epileptics of the galvanic current applied to the thyroid body, with the view of arousing the supposed defective function of the gland. The indifferent electrode was Erb's, the active one was about four and five-eighths inches square, and each was applied alternately upon each half of the thyroid body. Each sitting lasted from one to five minutes; the force of the current varied from two to ten milliampères. Under the influence of the current, there was observed in three cases a manifest tendency to sleep; and, in all the patients, a hyperæmia of the face, especially notable in two cases. The diameter of the pupils remained unchanged.

This galvanic treatment was tried in seven cases, with the following results: In three patients, no modification, either in the number or in the intensity of the paroxysms, nor yet in the psychic state. In the four others, at first increase and then rapid and progressive diminution of the number of paroxysms, which even ceased altogether for a month in one patient, and for two months in another. In the case in which the number of attacks had diminished, there was remarked in addition a favorable modification in the character of the paroxysms. Thus, the aura and the other prodromic phenomena, very marked before the treatment, disappeared after the sittings of galvanization; the duration and intensity of the attacks diminished; the tonic convulsions were no longer observed. There was thus demonstrated a marked amelioration in the post-epileptic phenomena and in the character of the patients, who, after each paroxysm, recovered their consciousness much more quickly than before. The mental dulness diminished, the taste for work increased, the patients became less violent.

Combined Chloroform and Cocaine Anæsthesia.

Professor Obalinski, of Cracow, says the *Lancet*, August 4, 1888, remarking the antagonism between chloroform and cocaine, determined to take advantage of it in anæsthesia for operative purposes. He has now employed the combined chloroform and cocaine method in twenty-four cases, with, as he states, the most satisfactory results. He first administers chloroform by means of an Esmarch's mask until the stage of tolerance is reached, which is generally in from four to twelve minutes, with the use of from one to three drachms of chloroform. He then injects into the region about to be operated on a solution of cocaine of the strength of from 3 to 5 per cent., the total quantity of cocaine injected being from three to five sevenths of a grain. Even more than this might, he thinks, be safely used, both because chloroform is the best antidote to cocaine and because part of the cocaine is about to be removed from the body by the operation. After the injection, no more chloroform is as a rule given, unless in protracted operations, when very small quantities are administered at considerable intervals. For this method, several advantages are claimed, amongst

others the following: A smaller quantity of chloroform is sufficient; vomiting is very rare; the depression on awaking is much slighter than when chloroform alone is used. The only disagreeable symptoms which Professor Obalinski has observed have been excitement and throwing about of the arms in some nervous people; but, as this occurs when chloroform alone is used, it is not at all certain that it ought to be ascribed to the cocaine. He recommends the combined method for extensive operations, finding the local use of cocaine usually quite sufficient to render minor operations painless.

Climate in Graves' Disease.

B. Stiller, of Budapest, has an interesting essay on this subject in the *Wiener med. Wochenschrift*, No. 27, 1888, in which he reports the very favorable results which he obtained from the high-altitude treatment in two cases of Graves' disease. We learn from the *Deutsche med. Wochenschrift*, August 16, 1888, that the first patient was a woman of weak nervous system, who was disturbed by family catastrophes, and finally developed a well-marked Graves' disease, which was preceded by symptoms of hysteria and neurasthenia. In addition to the specific symptoms of the disease, there was hypertrophy of both sides of the heart, associated with a systolic murmur. In 1874, she was sent to Preblau, in Kärthen, which is 3000 feet above sea-level. Here her pulse fell from 120 to 70 or 72, and remained steady at that number; the exophthalmus also subsided. In the winter, however, on returning home, the patient relapsed. In the winter of 1879, all the symptoms of heart-failure, together with unusual dilatation of all the arteries, occurred; the condition was desperate; digitalis failed utterly. Urged by relatives, she again, in spite of her condition, sought a cure at Schmeck's (3000 feet above sea-level).

She bore the journey, and after two months came home much improved, without dropsy, nor did dropsy recur. In the last few years there have occurred, as complications, acute circumscribed œdema, transient attacks of aphasia, and, in the winter of 1883, while on the Riviera, a peculiar apopletic attack. Winter before last, there occurred a very threatening change in the action of the heart, accompanied with irregularity, weakness, very rapid pulse, etc. Last summer she again went to Schmecks, and returned strengthened so as to be able to withstand several occurrences which were calculated to weaken her.

In another case analogous to the one just described, Stiller caused the patient to seek a high climate in winter, with excellent results. This patient was also a woman, and was forty-three years old. Stiller does not give a physiological explanation of this action of the climate of an elevated region, but raises the question whether or not it may be tried with success in other forms of heart-disease in the stage of disturbance in compensation.

Spinal Manifestations of Gonorrhœa.

In a communication in the *Revue de Médecine*, No. 6, 1888, Drs. G. Hayem and E. Parmentier say that, as the idea of infection is to-day intimately connected with the word gonorrhœa, one is led to charge to the account of this general infection certain complications which appear in the course of gonorrhœal urethritis. Among these, certain nervous disorders of spinal origin have attracted the attention of a small number of observers such as Stanley, Gull, Everard Horne, Tixier, Peter, and Ricord; but they have not up to the present time received a very satisfactory interpretation, and have been confused, at least in part, with some of the manifestations of sciatica. Hayem and Parmentier take up the question again. Relying on previous observations and upon some of their own, they show that, in some cases of gonorrhœa, spinal phenomena are met with, such as girdle pain, lightning pains in the lower limbs, double sciatica, hyperæsthesia, exaggeration of the patellar reflex, epileptoid trembling, impairment of mobility, and atrophy of the muscles of the legs and thighs. True paraplegias have been noted. These phenomena appear usually during articular and synovial complications, accompanying them through the periods of recrudescence and decline, so that the notion of simple coincidence is excluded, and present, likewise, a period of appearance variable in accordance with the onset of the gonorrhœa. These spinal complications may be grouped in three categories: disturbances of sensibility; disturbances of sensibility and of mobility together; and disturbances apart from mobility, paraplegia in different degrees. They affect, moreover, exclusively the lower limbs, and appear especially in the form of a congestion of the cord, of a meningo-myelitis involving more or less the posterior or postero-lateral portion of the cord. One must, however, take

into account the inflammatory irritation which may affect the nerve-roots crossing the spinal membranes, and, perhaps, as Velpeau has noted, of the compression or direct irritation of these roots in the course of vertebral arthritis.

To sum up, among the spinal complications whose cause has been hitherto undetermined, there are some which proceed directly from gonorrhœa. Hereafter, spinal complications should be included among the exceptional localizations of the gonorrhœal infection.—*Gazette Hebdomadaire*, July 27, 1888.

Prognosis in Diseases of the Respiratory Organs in Children.

Dr. Jules Simon (*Journal de Méd. et de Chir. Pratique*, March, 1888) says: We know of the gravity that may attach to simple coryza in the new-born child, and how it prevents nursing and troubles its sleep, while, should it become chronic, it may give rise to serious lesions. Coryza, too, is much more serious in infants than when it occurs later as a secondary condition following rubeola, or is dependent upon syphilis.

Laryngitis may show itself in a new-born child under peculiar aspects, and with such intensity as to give the appearance of croup, thus reminding us of spontaneous croup, though this is almost unknown in early infancy. The child, who appears to be suffering from a common cold, is suddenly seized with violent dyspnœa, and this gives rise to epigastric depression on each inspiration, and sometimes to suffocation. We must remember that, if stridulous laryngitis does not attack the new-born child, he is certainly liable to forms of laryngitis with spasmodic phenomena which are much more prolonged than in the latter. Briefly, the forms of laryngitis are sufficiently varied in the infant to suggest great reserve in prognosis.

Tracheitis in children over two years of age is more frequent than is generally supposed. It is often accompanied by spasmodic symptoms without involving either the larynx or the bronchia. The patients often have a spasmodic cough that might easily be referred to pertussis or false croup. The prognosis is usually good.

The prognosis of broncho-pneumonia varies widely in accordance with its many forms. These may be divided into three groups. In certain cases it may be rapidly fatal; in a child which at first appears to have no more than a light form of bronchitis, the symptoms become suddenly more marked, and their intensity is sometimes so great as to cause death within two or three days. The subacute form is oftener seen; it continues for eight or ten days, and is not usually dangerous. It differs from the third form, which also is of slow development, and may last for a month or more. Its chief characteristic is its irregularity, for, during its continuance, it gets better and worse, and makes the prognosis absolutely uncertain. Its course is somewhat as follows: During the first eight days, the issue seems destined to be fatal; then there is an amelioration in the general condition, the fever diminishes, and the signs of pulmonary induration give way. This mobility is a good sign. Then a new aggravation follows, and, after many alternations, the patient—provided its friends have not grown tired of medical intervention—gets well. From a prognostic point of view, it may be said that broncho-pneumonia, so serious in its rapid forms, is curable in fifty per cent. of the cases whose course has continued from ten to fifteen days.

It is a rule that, when a child presents an inexplicable febrile condition, to examine its throat, even if no symptom is present which may point to respiratory troubles; but, if no knowledge is gained from such examination, the state of the kidneys should be ascertained. Congestions in this region are very frequent in infants, and are shown by a certain degree of albuminuria and a more or less pronounced œdema. At the same time, anasarca, without albuminuria, is not rare in infants. Often, also, partial and motory œdema, referable to nephritis, is difficult of differentiation from that brought about by other affections. In pertussis, for instance, there is often an œdematous tumefaction of the face; it nevertheless presents this peculiarity, that it is firm, and is accompanied by a certain degree of coloration which is not found in œdema of renal origin. This œdema of pertussis may be compared with that produced in bronchic adenitis, and it may also be confounded with that which almost always exists in pertussoid cough.

Finally, partial œdema of the neck is often pathognomonic of diphtheria. It is not rare in children's cases to observe that, while there is no sign of angina and no pain, there is an œdematous swelling of the neck and the inferior portion of the face, which we must know how to recognize as being characteristic of this malady. As to œdema of cardiac origin, it is the last diagnostic point we have to think of in children's

cases, for, when it shows in them at all, the signs of heart-affection are so well developed that they cannot be misunderstood.—*New York Med. Abstract*, May, 1888.

Congenital Ectocardia.

At the meeting of the *Société médicale des Hôpitaux*, July 13, 1888, M. Huchard presented a woman, 36 years old, who had congenital ectocardia. The heart pulsates in the epigastrium, where it can be grasped with the hand. The alternate contraction of auricles and ventricles can be seen very distinctly. A curious fact is that the pulsations of the heart are perceived better above the heart than on a level with it. This malformation proceeds from an arrest of development of the lower part of the sternum, and of the upper part of the muscles of the abdomen.

The woman had had four confinements. Since the last, the deformity has become pronounced, and the heart more prominent than it was before. Below the heart is a large hernia, which has a tendency to increase. M. Huchard proposes to have an apparatus made to protect the heart and retain the hernia.—*Bulletin Médical*, July 18, 1888.

Traumatic Diaphragmatic Hernia.

Mr. James W. G. Farwell reports a case of this kind in the *Lancet*, June 30, 1888, which he thinks is remarkable in that the patient lived sixteen years after the accident. It seems that Mr. Farwell was sent for, one evening, to see a man who had been caught between the bumpers of two cars, which he had just uncoupled, the blow striking him in the abdomen. No bruising of the skin of the abdomen was apparent, no ribs were fractured, there was no dyspnœa, but great collapse. From the latter, however, he soon recovered. Every now and then, he experienced sudden paroxysms of pain, acutely spasmodic in character, and referred to the abdomen. This pain occurred chiefly when he was in bed, and, while it lasted, the muscles were very rigid. These paroxysms continued for several weeks, but there was no sickness, dyspnœa, or any other bad symptom. He recovered sufficiently in six weeks' time to resume work, but he now acted as night-signalman, which post he held until his death, sixteen years afterward. He walked daily five miles to and fro to his duties, and, when at home, was able to look after his garden. During this time he enjoyed good health, only occasionally suffering with slight dyspepsia, which yielded readily to simple remedies. One feature may be noted: his complexion became muddy in color, the lips blanched, the tongue bloodless, all of which Mr. Farwell thinks pointed to splenic mischief. Sixteen weeks before death, the dyspepsia grew worse, and he had rigors simulating attacks of ague, and the bowels were very relaxed. One month before death, Mr. Farwell was called to see him, and found him suffering great pain from flatulent distension of the abdomen; pulse weak and frequent; skin cold and expression anxious; no dyspnœa, cough, or vomiting, but much purging, the motions being of a dark color. These symptoms increased in severity, and he sank gradually, being unconscious for some hours before his death.

At the autopsy, the stomach and some of the small intestines were found lying upon the left lung, which was only one-fifth its usual size, but otherwise healthy. Both stomach and intestines were enormously distended with flatus. The liver was pale, the left lobe being atrophied; spleen very flat and pale, and much thinned. A large opening was found in the diaphragm, through which three fingers could easily be passed. The heart was pale and flabby.

Treatment of Rupture of the Uterus.

At the meeting of the Second Congress of the German Gynecological Society, at Halle, May 26, 1888, Dr. Leopold, of Dresden, read a paper on treatment of rupture of the uterus, in which he said that he had met this accident five times in 6100 births; in four cases it was complete, and in one incomplete. He concludes that delivery should be undertaken in the way that is best for the mother. If the child has been in great part or wholly thrown into the abdominal cavity, laparotomy alone should be considered. Even if there is an opportunity to extract by the feet, this should not be done, as traction may make the injury to the uterus greater. A binder accomplishes good in some cases, and sufficient drainage should be provided. In discussing Dr. Leopold's paper, Dr. Battleher, of Carlsruhe, asked whether or not, in a case in which pregnancy occurred after recovery from rupture of the uterus, a Cæsarean section should be made. He had, after a rupture of the uterus, twice done the Cæsarean operation in the same woman with good results. His advice is, not to wait till the end of pregnancy.—*Deutsche med. Wochenschrift*, July 26, 1888.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D., EDITOR.

The Terms of Subscription to the serial publications of this office are as follows, payable in advance:

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium, - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.25**
Reporter and Pocket Record, - - - -	**6.00**
Reporter, Compendium, and Pocket Record,	**7.00**

All letters should be addressed, and all checks and postal orders drawn to order of

Drs. RANDOLPH & DULLES,
N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper large letter size.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate, or omit words like "the," and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

During the week just ending, an event has occurred which marks an era in the history of medicine in the United States. The gathering in Washington of the members of eleven national societies, made up of men chosen for membership by reason of their attainments as general or special practitioners, and their organization into a Congress, is an event which cannot fail to have a most important influence upon the whole profession. Gathered from the North and South, the East and West, this body included a very large proportion of those who have attained distinction, at home and abroad, for their scientific attainments and their skill as practitioners. In a country so vast as ours, it is not to be expected that any organization can bring together all who might fitly be included in it; but the Congress which has just held its first session came as near to this as could be expected at this time. The names enrolled may be compared without fear with those which appear in the roll of any national association of medical men in any part of the world, and the proceedings of the Congress have rarely been equalled for scientific value or practical worth. American physicians and surgeons may well be proud in contemplating what these their representatives have accomplished, and follow with hearty good wishes the sequel of so auspicious a beginning.

So much of the Congress itself. But there is an aspect of this event which is likely to attract almost as much attention as that to which we have just alluded. This aspect is the relation which the Congress of American Physicians and Surgeons will bear toward the American Medical Association. It is no secret that a number of the members of the latter body regard the Congress as a rival, and its success as likely to injure the Association. Time alone can decide whether or not this feeling is well founded; but we hope that it may prove to be unfounded. We believe that it will prove unfounded, if those who are attached to the Association make no mistake as to the relative spheres of the two bodies. As we understand the matter, there should be no rivalry between them, except such a generous rivalry in scientific attainments as is compatible with entire harmony of feeling. It is pleasant to note, among the members of the Congress, a number of men who have contributed in the past to the best work of the Association, and who may be expected to add lustre to its future proceedings.

In the nature of things, it is to be expected that the Congress will attract more scientific papers than the Association, and that it will require great judgment and great labor to keep the scientific standing of the Association on a level with that of the Congress.

Indeed, it is not unreasonable to fear that the scientific proceedings of the Association may never compare, in the eyes of unprejudiced men, with those of the Congress; but, even if this fear should be realized, the work of the Association need not come to an end.

It must not be forgotten that one of the most important parts of the mission of the Association is to bring together a large number of the medical men of our country in friendly and social intercourse. The constitution of the Congress is, to a certain extent, exclusive; the constitution of the Association is intended to include all the reputable physicians of the United States. The latter is the body in which all may gather to promote unity of feeling and harmonious regard between the rank and file of the profession.

This is the office of the Association which we believe deserves the greatest consideration just now; and we trust that those who feel most seriously that the meeting of the Congress marks a crisis in the medical affairs of our country will regard the circumstances with calmness and judgment, and be incited by them to earnest endeavors to make the Association more dear than it has ever been in the past to the hearts of all right-minded men. If this be done, the success of the Congress and the success of the Association will go hand in hand, and each body will fill out the measure of the other's usefulness.

TRANSPLANTATION OF SKIN FROM A CORPSE.

The attempt to transplant skin from a dead body to a living one on the human subject was first made, we believe, in this country a few years ago. The success obtained was such as to encourage further attempts, but we are not aware that such attempts have been systematically carried out. At the time of this operation, we hoped that it might soon be repeated, and that America might have an undisputed claim to the credit of so bold and singular an enterprise. But the operation seems not to have been followed up, and now a report comes from Germany which is likely to imperil the claim of our country for having originated it.

In the *Berliner klinische Wochenschrift*, August 6, 1888, Dr. Bartens, of Roda, reports the case of a boy, fourteen years old, who came under his care for the treatment of deep burns of the foot, which had destroyed almost all the skin on the upper surface of both feet and of the legs near the malleoli. After failing to secure regeneration of the skin by other methods, he decided to try transplantation. The condition of the patient was so unfavorable that Dr. Bartens could not use his skin for this purpose, and no donor was at hand. He therefore took two large pieces of skin from the calf of the leg of a man seventy-five years old—who had just died—within twenty minutes after his death, laid them in lukewarm water to which a little common salt had been added, carried them to the bedside of the patient, freed them from their subcutaneous fat, cut them into pieces about one-third of an inch wide and from one-third to two-thirds of an inch long, and laid them on the ulcerated surfaces after these had been carefully washed with warm water. The whole of the fields of operation was now sprinkled with iodoform and covered with a cotton dressing. The whole operation lasted for an hour and a half after the death of the man from whom the skin was obtained. Each foot received fourteen grafts. After six days, the first dressing was removed, and it was found that twenty-four of the twenty-eight grafts had become attached. The surfaces were washed with a weak solution of permanganate of potash, and covered with a dressing like the first. Four days later, this was removed, and the grafts found to be doing well, and to be sensitive to needle-pricks and light touching. In due time, the whole of the ulcerated surfaces was covered with good skin, and this was so elastic that the patient could run and

execute all movements of the foot without difficulty.

This admirable and remarkable result must surely attract wide-spread attention to the method of transplanting skin from a dead body to a living one. There seems to be no good reason why it should not be entirely practicable, and we hope it will be taken up again on this side of the sea. The idea of thus incorporating into a living body portions of one which has ceased to live, as a body, is very curious, and suggests reflections which have nothing to do with surgery, especially when, as in the case just described, the body is that of one who has passed the age of three-score years and ten. But we have to do now only with the surgical aspects of the case, and commend it to the attention of our readers for its practical uses only.

THE STUDY OF CHILDREN'S DISEASES.

In an excellent editorial, the *British Medical Journal*, August 18, 1888, calls attention to the importance of studying the diseases of children, as distinguished from those of older persons, and congratulates the British Medical Association that after a lapse of five years this subject has been deemed important enough to be considered by a special section. It is quite true, as is stated in the editorial referred to, that children's diseases are not a specialty in the same sense that diseases of the eye or those peculiar to women are, and it is to be hoped the day may never come when they will be so regarded. Such an idea will be opposed by none more vigorously than by those who have made a special study of them. Children are but men and women in miniature, and this is quite as true of them in regard to diseases as to the ordinary affairs of every-day life. With the exception of the preliminary troubles in reference to feeding and the disorders connected with, and perhaps arising out of, the developmental processes of the first two years of life, there is little difference between the diseases of children and those of adults, save that the former are less liable to be complicated by the previous habits of the patient, and are therefore so much the easier to recognize and also the more amenable to treatment.

To this presentation of the case, more might be added by those who have made a study of the peculiarities of the vegetative functions in children and of their mental and nervous development. When all is considered, there will be no hesitation, in this country, in agreeing with the *British Medical Journal* that the diseases of children deserve to be made the object of special study in medical schools. To this we would add that they ought, more perhaps than the diseases of adults, to be made the subject of clinical instruction. Those who have had the advantage of seeing the way in which Monti, in Vienna, teaches his students how to diagnosticate and treat the diseases of little children must always hope that in our own country some such method will be adopted to instruct the rising generation of medical men in the rare art of dealing kindly, wisely, and successfully with the little ones.

The principle of regarding with due consideration the diseases of children as a sort of specialty—a sort which every practitioner must learn—is not ignored in America; but something remains to be done, we think, in applying it. The time is gone, never to return, when one professor was supposed to be able to teach, in two courses of lectures, obstetrics and the diseases of women and children; and we may expect that before long the diseases of children will be taught as they ought to be all over the civilized world.

MEDICAL DOGBERRYS.

Not long since, some stir was made in Philadelphia over a case of suspected cholera, and the way in which it was dealt with by the health authorities. According to the

published reports in regard to it, a friendless person was taken sick, somebody declared the disease was cholera, the Health Officer was informed of this by telegram, and he at once issued an order for the removal of the patient to the Municipal Hospital for contagious diseases. The victim was really suffering with cholera morbus, and died before the order could be carried into effect. Some zealous persons at about this time, not content with the authority lodged in the Health Officer, proposed the passage of a law giving to the Lieutenants of Police authority to order the removal of persons believed to be suffering with a contagious disease to the Municipal Hospital. The object contemplated by the proposers of this law is an excellent one; and it is quite possible that their idea of the way to effect it was wiser than appears on the surface. Still, in the form suggested, it could not be approved by persons of discretion. It is well that the health authorities of any city should have power to isolate persons likely to spread a contagious disease; but the authority needs to be exercised with unexceptionable prudence, or it would constitute an intolerable invasion of the rights of citizens.

From what occurred in the case referred to, it appears that even an officer specially authorized to discharge this function may be carried away by fear and false information, and use it unwisely and dangerously. Under these circumstances, it is very clear that his authority ought not to be extended to persons entirely unfamiliar with matters of health and the science of medicine. Such persons could not fail to be medical Dogberrys, and no amount of lecturing to them in police stations would make them anything but a nuisance and oppression to those whom they are intended to defend and protect. As it is, there is some ground for believing that individuals from whom better things might be reasonably expected are at times very like medical Dogberrys, and that they sometimes get hold of the middle part of the old injunction "*tuto, cito, et jucunde*," when it would be better if they had a good grip on its extremities.

PAMPHLET NOTICES.

We call the attention of our readers to the department of "Pamphlet Notices" in the REPORTER, which is intended to serve a double purpose: first, to give the readers of the REPORTER a systematized *résumé* of the medical papers which are reprinted and made available for those who do not see the journals in which they originally appear; and second, to bring their authors and our readers into closer relations, for their reciprocal pleasure and profit.

It is pleasant to have—as we have had—evidence that both these objects are being attained; and we expect that this department of the REPORTER will prove an interesting and useful one. In concluding, we beg our readers, who write for these reprints, not to overlook the suggestion printed at the head of the column of Pamphlet Notices, and *always* to enclose a postage-stamp with the request for a copy. This is the least which can be done by those who ask the favor, and who ought to make it as easy as possible for the author to grant it.

SHAM MEDICINES.

Amid the confusion caused by the claims of various preparations presented to the public as remedies for disease, and the charges made against them, there is great advantage in having them analyzed by competent and disinterested persons. A great variety of such remedies has been examined by Dr. B. F. Davenport, the Analytical Chemist of the State Board of Health of Massachusetts, and the results of his analyses are published in the *Boston Journal of Health*, September, 1888. The results of his analyses of a number of so-called opium-cures and tonics and bitters we republish in another part of this number of the REPORTER, and invite the attention of our readers to them, for their own information and that of their patients.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

INTRACRANIAL TUMORS. By Byrom Bramwell, M.D., F.R.C.P.E., F.R.S.E., Lecturer on the Principles and Practice of Medicine in the Extra-Academical School of Medicine, Edinburgh, etc., with one hundred and sixteen illustrations. Philadelphia: J. B. Lippincott Company, 1888. 8vo, pp. xiv, 270. Price, $4.50.

There have been few books issued from the medical press of this or any other country which can compare with this magnificent volume. It is printed in the most admirable way, and its illustrations are unusually fine. The latter include such beautiful engravings and reproductions of photographs, showing the macroscopic and microscopic appearances of a great variety of morbid conditions of the brain and its adulxa, that it is hard to find words to express the admiration they excite. And these attractions of the book are entirely in keeping with the scientific merits of its contents. Dr. Bramwell is well known as a careful observer and an able writer, and his reputation—already sufficiently established—will only be enhanced by this work. No careful student of brain-pathology can afford to be without it, and we can recommend it in the most unqualified terms to the attention of our readers.

DIE TECHNIK DER MASSAGE. Von Dr. Albert Reibmayer. (THE TECHNIQUE OF MASSAGE. By Dr. Albert Reibmayer.) Third edition, enlarged and improved, with 162 wood-cuts. Leipzig and Vienna: Toeplitz and Deuticke.

This volume gives in concise form a full and instructive account of the various manipulations included under the general term "massage." The simple manipulations are first described, the clearness of the text being much enhanced by the numerous cuts. The massage of several of the more important regions of the body is then taken up, the massage of the uterus receiving special attention. Then come chapters on massage of the whole body; a description of the instruments and apparatus used; and a chapter on "General Remarks," which embodies the author's conclusions. A systematic account of active and passive motion properly ends the book. The author's style is clear and readable, and gives additional ground for recommending the work to those of our readers familiar with German.

PARTIAL SYLLABIC LISTS OF THE CLINICAL MORPHOLOGIES OF THE BLOOD, SPUTUM, FECES, SKIN, URINE, VOMITUS, FOOD, ETC. By Ephraim Cutter, M.D., Etc. 8vo, pp. 81. New York: Published by the author, 1888. Price $1.00.

Most persons who take this book in hand will probably be disgusted at the outset by the vanity and desire for self-aggrandizement apparent on the title-page, which is crowded with titles of the author and a list of his previous publications. Nor is this impression likely to diminish in turning over its pages, which contain a great deal which might perhaps be put to a useful purpose by one of a judicious mind, but which here is simply tiresome. It is a pity that one who is so industrious and persistent as Dr. Cutter should not be more fortunate in his manner of presenting his views to his professional brethren.

Pamphlet Notices.

[Any reader of the Reporter who desires a copy of a pamphlet noticed in these columns will doubtless secure it by addressing the author with a request *stating where the notice was seen* and enclosing a postage-stamp.]

Drug Interference. By Thomas J. Mays, M.D., Philadelphia. From the *Therapeutic Gazette*, May, 1888.

Stricture of the Urethra; Urethrotomy Under Cocaine Anæsthesia. By Henry J. Reynolds, Chicago. From the *Western Medical Reporter*, April, 1888. 14 pages.

Note on the Treatment of Syphilis by the Hypodermatic Injection of Calomel. By J. C. Wilson, M.D., Philadelphia. From the *Medical News*, June 2, 1888. 18 pages.

—Dr. Mays presents, in this paper, a study of the effects of maximum and minimum doses of certain drugs upon the action of the frog's heart. These effects are illustrated with tracings, and suggest interesting thoughts in regard to the operation of the drugs used, as well as in regard to the general question of therapeusis. Dr. Mays states the ideas which they have suggested to him; and, while these may not be regarded by all who read them as a necessary conclusion to his premises, they are worthy of serious consideration, especially as examples of a habit of thoughtful observation which may be commended to all who desire to enrich the science of medicine by some good work of their own.

—Dr. Reynolds's pamphlet contains a reprint of a clinical lecture delivered at the College of Physicians and Surgeons of Chicago. In it the steps taken in examining and operating upon a case of stricture are well described, and the operation of internal urethrotomy is especially recommended.

—Dr. Wilson describes clearly and succinctly the method of treating syphilis with hypodermic injections of calomel, which is, of course, familiar enough to all who are conversant with the modern German literature of venereal diseases, but which has never been brought prominently to the attention of the medical profession in this country. This method has given very satisfactory results in the hands of a number of European physicians, and has much in its favor. Dr. Wilson reports the results he has obtained in the treatment of twelve cases, and describes admirably the way in which this method should be carried out, stating very fairly its advantages and its occasional disadvantages.

Literary Notes.

Scribner's Magazine gets more interesting and attractive all the time. The articles on railways, which are the leading feature just now, are admirably written and magnificently illustrated, and the merit of the other articles is in keeping with the general high tone of the magazine.

The number for June contains an article on hospital life, which must interest the lay readers very much; but it has a special charm for those whose experience makes them familiar with the working of the ambulance system in large cities, and the inside history of hospitals.

CORRESPONDENCE.

Milk Inspection.

TO THE EDITOR.

Sir: In your editorial on "milk inspection," in the REPORTER for September 8th, occurs the following: "A tour of inspection among the retailers of milk to the poor would, we think, do more to correct the horrible cheating, etc." Now that is precisely what Dr. Nevins does, in addition to his descents upon dealers as they load their wagons at the railway stations, or drive off the ferry-boats. It has been my privilege to accompany him on one of his daily tours among the "shops" on the East Side, and I can testify to the thorough and fearless manner in which he performs his by no means pleasant duties. You say truly that he is "a most efficient and zealous public officer."

This is written more for the purpose of supplying information, the absence of which is indicated in the editorial referred to, than for publication, yet I have no objection to the latter use being made of it, if it pleases you so to do.

Yours truly, OBSERVER.

New York,
September 11, 1888.

Epilepsy—A Case.

TO THE EDITOR.

Sir: If space will permit, let me report the following case of epilepsy, which has been of several years' duration.

In the early part of May last, I was consulted, as a "new doctor" recently located in this town, by a young woman 19 years old, suffering from scrofula, and, as a sequel or resultant, with epileptic attacks of the *grand mal* type. The latter were of frequent occurrence and varied in number from one to three a day. I learned from the patient her family history, which, so far as she or her relatives could give, was good. This young woman first gave signs of scrofula when 12 years old. It grew constantly worse until she was 14, when she began to have epileptic attacks. From then until May 15, two weeks after coming under my care, it was never safe to leave her alone.

My first prescription for her consisted of the bromides in large doses. As she told me she had tried many doctors, all of whom prescribed some one of the bromides, I also ordered for her syrup of the iodide of iron in fifteen-drop doses. This I kept up for two weeks, but failed to see any benefit. I then gave the following:

℞ Potass. bromid. . . . . ℥i
Sodii bromid. . . . . ℥i
Tinct. belladon. . . . . f℥ss
Aquam . . . . . q. s. ad f℥vj
M. Sig. Teaspoonful after each meal. *To be increased.*

For the scrofula, I ordered syrup trifolium comp. in large doses. From the first days of these prescriptions, her condition changed, and she is to-day a comparatively new woman. Her catamenial flow was irregular, but is now normal. Her looks, habits, etc., promise a permanent cure.

Yours truly, J. R. HUNTT, M.D.

Laurel, Md.,
September 2, 1888.

NOTES AND COMMENTS.

Bad Drainage and Suits for Damages.

The *Lancet*, August 4, 1888, comments on a suit for damages, which may be of medico-legal interest to readers on this side of the Atlantic. It seems that a case came before the Court of Appeal, in which the plaintiff had bought a house from the defendant; the latter, in answer to an inquiry as to the state of the drains, stated that he had spent $240 in putting them in order. Relying on this statement, the house was purchased; but soon three members of the plaintiff's family were suffering from enteric fever. On this occurrence taking place, the drains were opened up, and a condition of things was discovered which involved, amongst other things, the removal of forty cart-loads of sewage-contaminated earth. For the alleged misrepresentation, the illness, the alterations, and the consequent expenditure, the plaintiff sought relief; but the jury found for the defendant, on the ground that he had been as much deceived by the builder as the plaintiff, and that there had been no fraudulent misrepresentation. The Divisional Court refused a new trial, and this refusal has been confirmed by the Court of Appeal, mainly on the ground that there had evidently been no wilful deception on the part of the defendant. The case, remarks the *Lancet*, is instructive as showing the limit of responsibility as regards persons selling or letting houses in the present state of the law, and as indicating the desirability, on the part of persons buying or leasing house-property, of securing a definite warranty from the owners as to the sanitary conditions of the property before purchase.

Sham Medicines.

Opium "Cures."—Dr. B. F. Davenport, Analytical Chemist of the Massachusetts State Board of Health, says he has found by analysis that the twenty varieties of "cures," all of which contain opium, are as follows:

H. L. Baker, Toledo, Ohio.
J. C. Beck, Cincinnati, Ohio.
Chas. C. Beers, New York City.
Geo. A. Bradford, Columbus, Ga.
P. B. Bowzer, Logansport, Ind.
J. S. Carleton, Chicago, Ill.
S. B. Collins, La Porte, Ind.
B. S. Dispensary, Berrien Spring, Mich.
J. A. Drollinger, La Porte, Ind.
J. R. A. Dunn, Elizabeth, N. J.
J. C. Hoffman, Jefferson, Wis.
H. H. Kane, New York City.
L. E. Keeley, Dwight, Ill.
F. E. Marsh, Quincy, Mich.
L. Meeker, Chicago, Ill.
Wm. P. Phelan, Chicago, Ill.
Salvo Remedy, New York City.
W. B. Squire, Worthington, Ind.
J. L. Stevens, Lebanon, Ohio.
B. M. Woolley, Atlanta, Ga.

"Tonics" and "Bitters" Containing Alcohol.—Beer and ale contain from three to seven per cent. of alcohol. In sherry wine there is from eighteen to twenty per cent., and in whiskey and brandy fifty per cent. of alcohol. Now, nearly all the patent medicine "tonics" and "bitters" contain a large amount of alcohol; hence it is easy to be seen why the indulger in what he considers "his medicine" "feels better."

The following are Dr. Davenport's analyses—for alcohol—of a number of tonics and bitters on the market. The per cent. given is of alcohol:

Carter's Physical Extract, Georgetown, Mass. Dose, one tablespoonful, three times daily. 22 per cent.

Hooker's Wigwam Tonic, Haverhill, Mass. Dose, one tablespoonful, three times daily. 20.7 per cent.

Hoofland's German Tonic, Philadelphia. Admitted to contain Santa Cruz rum. Dose, wineglass, four times daily. 29.3 per cent.

Hop Tonic, Grand Rapids, Mich. Dose, one tablespoonful to wineglass, three times a day. 7 per cent.

Howe's Arabian Tonic, New York. Advertised as "not a rum drink." Dose, tablespoonful to wineglass, 4 times daily. 13.2 per cent.

Jackson's Golden Seal Tonic, Boston. Admitted to contain Marsala wine. Dose, half a wineglass, three times daily. 19.6 per cent.

Liebig Co.'s Coca Beef Tonic, New York. Advertised to be made "with sherry." Dose, two to four teaspoonfuls, three times daily. 23.2 per cent.

Mensman's Peptonized Beef Tonic, New York. Acknowledged to contain spirit. Dose, one to three tablespoonfuls, three times daily. 16.5 per cent.

Parker's Tonic, New York. Claimed to be purely vegetable extract. "Stimulus to the body without intoxicating." "Inebriates struggling to reform will find its tonic and sustaining influence on the nervous system a great help to their efforts." Dose, as a tonic, one to two teaspoonfuls, one to three times daily. 41.6 per cent.

Schenck's Sea-Weed Tonic, Philadelphia. Claimed to be "distilled from seaweed after the same manner as Jamaica spirits is from sugar-cane. It is therefore entirely harmless, and free from the injurious properties of corn and rye whiskey." Dose, half wineglass three times daily. 19.5 per cent.

Atwood's Quinine Tonic Bitters, Boston. Dose, half tablespoonful to half wineglass, mixed with water, wine, or spirit, three times daily. 29.2 per cent.

L. F. Atwood's Jaundice Bitters, Portland, Me. Dose, half tablespoonful to half wineglass, one to six times daily. 22.3 per cent.

Moses Atwood's Jaundice Bitters, New York. Dose, half tablespoonful to wineglass, one to six times daily. 17.1 per cent.

H. Baxter's Mandrake Bitters, Burlington, Vt. Dose, one to two tablespoonfuls. 16.5 per cent.

Boker's Stomach Bitters, New York. Dose not given. 42.6 per cent.

Brown's Iron Bitters, Baltimore, Md. Claimed to be perfectly harmless. "Not a substitute for whiskey." Dose, tablespoonful. 19.7 per cent.

Burdock Blood Bitters, Buffalo, N. Y. Dose, teaspoonful to tablespoonful, three times daily. 25.2 per cent.

Carter's Scotch Bitters, Georgetown, Mass. Dose, tablespoonful to wineglassful, as occasion requires. 17.6 per cent.

Colton's Bitters, Westfield, Mass. Dose, teaspoonful to two tablespoonfuls three times daily. 27.1 per cent.

Copp's White Mountain Bitters, Manchester, N. H. "Not an alcoholic beverage," according to the claims made for it. Dose, wineglassful. 6 per cent.

Drake's Plantation Bitters, New York. "Contains St. Croix rum." Dose, wineglassful three times daily. 33.2 per cent.

Flint's Quaker Bitters, Boston. Dose, teaspoonful six times daily. 21.4 per cent.

Goodhue's Bitters, Salem, Mass. Dose, half wineglassful. 16.1 per cent.

Hartshorn's Bitters, Boston, Mass. Dose, tablespoonful to half wineglassful. 22.2 per cent.

Hoofland's German Bitters, Philadelphia. Advertised to be entirely vegetable, and free from alcoholic stimulant. Dose, tablespoonful, four times daily. 25.6 per cent.

Hop Bitters, Rochester, N. Y. Dose, one to three tablespoonfuls, three times daily. 12 per cent.

Hostetter's Stomach Bitters, Pittsburgh, Pa. Dose, wineglassful, three times daily. 44.3 per cent.

Kaufmann's Sulphur Bitters, Boston. "Contains no alcohol," according to advertisement. Dose, tea to table spoonful. It contains no sulphur, but has 20.5 per cent. alcohol.

Kingsley's Iron Tonic, Northampton, Mass. Dose, one to two teaspoonfuls, three times daily. 14.9 per cent.

Langley's Bitters, Boston. Dose, half wineglass or more, three times daily. 18.1 per cent.

Liverpool's Mexican Tonic Bitters, Boston. Dose, half to full wineglass, three times daily. 22.4 per cent.

Oxygenated Bitters, New York. Dose, tea to table spoonful. Acid, but no alcohol.

Pierce's Indian Restoration Bitters, Boston. Dose, up to wineglassful, and to six times daily. 6.1 per cent.

Z. Porter's Stomach Bitters, New York. Dose, tablespoonful or more, several times daily. 27.9 per cent.

Rush's Bitters, New York. Dose, wineglassful, four times daily. 35 per cent.

"Dr." Richardson's Concentrated Sherry Wine Bitters, Wakefield, Mass. Dose, tablespoonful to half wineglassful or more, three times daily, "or when there is sensation of weakness or uneasiness at the stomach." 47.5 per cent.

Secor's Cinchona Bitters, Providence, R. I. Dose, half wineglassful, three times daily. 13.1 per cent.

Shonyo's German Bitters, Concord, N. H. Dose, tablespoonful to wineglassful. 21.5 per cent.

Job Sweet's Strengthening Bitters, New Bedford, Mass. Dose, tablespoonful to wineglassful, three times daily. 29 per cent.

Thurston's Old Continental Bitters, Lynn, Mass. Dose, teaspoonful to two tablespoonfuls 11.4 per cent.

Walker's Vinegar Bitters, New York. Claimed to be free from all alcoholic stimulants. "Contains no spirit." Dose, half to full wineglass. 6.1 per cent.

Warner's Safe Tonic Bitters, Rochester, N. Y. Dose, tablespoonful to wineglassful. 35.7 per cent.

Warren's Bilious Bitters, Boston, Mass. Teaspoonful to two tablespoonfuls, one to three times daily. 21.5 per cent.

Wheeler's Tonic Sherry Wine Bitters, Boston. Dose, two-thirds wineglass, twice daily. 18.8 per cent.

Wheat Bitters, New York. Dose, dessert to wineglass, three times daily. 13.6 per cent.

Faith Whitcomb's Nerve Bitters, Boston. Dose, tablespoonful, three times daily. 20.3 per cent.

Dr. Williams's Vegetable Jaundice Bitters, Lowell, Mass. Dose, half to full wineglass, once daily. 18.5 per cent.—*Boston Journal of Health*, September, 1888.

A Simple and Efficient Water-Filter.

Dr. F. A. Castle says, in the *N. Y. Medical Journal*, July 7, 1888: For a long time I have used, in my butler's pantry, a simple contrivance for filtering water used on the table, which has been so serviceable and at the same time so inexpensive that I venture to recommend it. I took an ordinary glass pharmaceutical percolator and packed the outlet with absorbent cotton so tightly that the water could only flow in drops. By means of a piece of copper wire for a bale, it was suspended from a hook on the lower side of one of the pantry shelves, over the shelf of the sink. As often as necessary, water is poured into the percolator, and the water-pitcher is placed under the outlet. Whenever the cotton shows much discoloration (a thing which is easily observed, owing to the percolator being of glass), the maid replaces it with fresh absorbent cotton. It is in all respects the most practical and cheapest filter I know of, and has no machinery to get out of order, no patent-right to carry, and the advantage over most filters that the filtering medium is always under observation, so that there is little risk of contamination of the water by accumulations of filth.

Prescription for Gastralgia.

Weissenberg's formula is (*Union Médicale du Canada,* July, 1888):

Hydrochlorate of cocaine . . . . gr. 1½
Extract of belladonna . . . . . gr. 7½
Powdered rhubarb
Extract of rhubarb . . . . . āā q. s.
M. Ft. pil. No. xx. Take one pill three times a day, at the moment of eating.

Pure Milk and Clean Dairies.

Dr. E. A. Wood, of Pittsburgh, who has devoted much attention to the study of milk, and how to obtain and to keep it pure, made the report of the Committee on Milk of the Allegheny County Medical Society, August 21. We give below some of his remarks upon this important subject:

Visit for yourself the dairy from whence you get your milk supply. Examine the cows, the stable, the kind of food the cows eat, the condition of the stalls, the method of milking, the vessels in which and the place where the milk is kept, and be sure and learn the length of time from the milking until it arrives at your door. Be your own milk inspector, is perhaps the most important advice which can be given you. You can detect faults in the groceries, or dishonesty in the grocer, but milk and the milkman are different from groceries and grocers. No other food requires such cleanliness and care in handling as milk, and no other tradesman has such hidden opportunities for wronging his customers.

The cow should be able to walk without halt or limp; the skin and hair should be soft and smooth and free from sores, tumors, and manure; the hoofs should be short and firm, and the cow itself in good flesh: if too fat, she is a beef and has been milked too long; if too lean, she is starving.

The cow-stable should be well aired and drained, and protected in winter. The cows should be stabled only in rough weather, and should never be chained, except at night in cold weather, when a warm stall is needed. In warm dry weather they should be free night and day, with sheds for shelter in case of storms. This rule would banish hundreds of narrow contracted dairies in our cities, and justly so. Shun the milk from cows that are stabled the year round as you would water putrid with carrion. Much milk is sold in our cities and towns from cows that are shut up in close and foul stables every night the year round, and, while most of them may be turned on goat-pastures for a few hours in the middle of the day, not a cow in the lot gives such milk as you should provide for your babe. Contrast such milk with the sleek cow's that stands in the country by day and sleeps through the dewy night in the glad fresh air.

The authorities should clean out many of our city dairies, the milk from which should not be used. The cow-stable would be all the better for being as clean as a kitchen, and, while this is perhaps impossible, the nearer approach to absolute cleanliness the purer and wholesomer the milk. But a certain amount of cleanliness is absolutely necessary. Stable-refuse in the stalls, and stench arising from any cause, will taint the best milk collected in the cleanest of vessels. Shun milk from stables that are foul with filth and stench. In good weather, the milking should be done in open clean yards, and, if possible, never in the stalls.

Milk that gets this fresh healthy start toward market will keep longer and better than milk fouled at the very instant of milking. There is a resisting power in such milk that enables it to endure the delay of the long and hot journey to your door. Do not buy milk from foul stables at any price. Milk from clean stables may cost you more, but you will save in the doctor's bill and may save an undertaker's bill.

If the dairyman refuses you an investigation, or even if he accords you a partial or reluctant welcome, shun him as you would a smuggler, and refuse his milk as you would the reception of stolen goods. His milk is not pure, and by buying it you encourage rascality and place an embargo on the honest milk dealer. The honest dairyman will court investigation, and not only welcome you, but aid you in every way to inspect his methods, the kind of food he gives his cows, the way he cleans and scalds and sun-dries his vessels, and the place where he keeps his milk.

There are a few bad signs you should note: It is a bad sign to see empty milk-pans and pails marked inside with the rings of former contents, or pans that give out a perceptible odor. It is a bad sign to see a greasy wagon or barrel about the premises, smeared with the grimy stains of putrid distillery-slop. It is a bad sign to see a churn about a milk dairy—the sign that the cream is stolen out of the milk sent to the customers. It is a bad sign to see meat or vegetables in the same room or in the ice-chest in which milk is kept. Finally, it is a bad sign to see untidy men and women about. Any one of these bad signs points unerringly to a faulty milk supply from that dairy.

Not Cruel if for Profit.

The London correspondent of the *New Orleans Med. and Surg. Journal*, August, 1888, says:

"A case recently before the Justiciary Appeal Court at Edinburgh gave occasion for a very neat illustration of the state of the law with regard to experiments on animals; the question was whether it was contrary to law to dishorn cattle; it was stated that the practice had been introduced from America, and consisted in sawing off the horns within an inch of the skull, the operation being extremely painful. In deciding that the operation was not illegal, Lord Young quoted the opinion that, 'if you opened an oyster for the purpose of eating it, that was lawful and quite right; but that, if you opened it for the purpose of science, it was against the statute and was a punishable offense.'"

Multiple Hunterian Chancres.

In the *St. Petersburg Vratch*, No. 30, 1888, p. 584, Dr. Lazar G. Volynetz, House Physician to the Alexandrovsky Hospital, in Kharkov, describes a curious case in which three syphilitic chancres were present in a strong and generally healthy fireman, 28 years old. The chancres appeared simultaneously about the eighteenth day after the patient's last coition. On examination on the twelfth day of the disease, there were found: (1) a typical Hunterian ulcer measuring 1 x ¾ centimetre, and situated on the lowest portion of the external fold of the prepuce, on the right side; (2) a cartilaginous induration, with a fresh central scar, of the size of a shilling-piece, situated on the left side of the internal fold of the prepuce; and (3) a somewhat smaller but similarly hard induration, with a recent cicatrix, situated on the lower aspect of the penis, near the scrotum. The inguinal, cubital, and cervical lymphatic glands were strikingly enlarged and hard, but indolent. Under the local application of a mercurial plaster, all the three primary indurations rapidly disappeared. Dr. Volynetz dwells upon the great rarity of cases of multiple syphilitic chancre, and mentions three other instances, namely: Ricord's case, in which there were nineteen hard chancres in a man, and Kaposi's two cases occurring in women, in one of which two ulcers occupied the lower lip, and in another the lower jaw.

The multiplicity of chancres, however, is not nearly so rare as Dr. Volynetz seems to suppose. Professor A. Gay, of Kazan, in his capital *Course of Venereal Diseases*, third edition, 1888, p. 268, says that, according to his experience, a single primary induration occurs in 86.4 per cent. of male patients, while in the remaining 13.6 per cent. the number of the chancres varies from two to twelve. Of 316 cases of the kind, he saw 2 chancres in 216 cases; 3 in 68; 4 in 14; 5 in 15; 6 in 2; 7 in 2; 8 in 2; and 12 in 1. In one of the cases, the ulcers were situated—one on the penis, another on the upper eyelid; in another, on the penis and the right forefinger; and in a third there were found two Hunterian chancres on the left cheek and one on the nose, the patient having been bitten by a syphilitic person.

The Pupil as a Guide in the Administration of Chloroform.

As a result of experiments upon animals and of observations made upon man, Dr. H. I. Neilson, in the *Riforma Medica*, June 23, 1888, formulates the following conclusions: 1. The first effect of chloroform narcosis on the pupils consists in a dilatation which varies in intensity and duration in different individuals. As the anæsthesia becomes more profound, the pupils then begin to contract, and finally become very small and immovable. If now the chloroform is pushed still further, a sudden dilatation occurs, which is the result of asphyxia, from which the patient seldom recovers; 2. As long as the pupil is observed to dilate in response to sensory stimuli, such as pinching the skin, the anæsthesia is not yet sufficient to allow the commencement of the operation; 3. As soon as the pupil becomes strongly contracted and immovable, the administration of the anæsthetic must be suspended until a commencing dilatation is observed, and the patient must be held at just this point as long as the operation continues; 4. Vomiting causes a dilatation similar to that occurring as the patient emerges from the narcotic condition, but it is usually more sudden in the former case. In experiments upon dogs, it was found that the contraction of the pupils did not begin until the blood-pressure was somewhat reduced, and that the dilatation proceeded *pari passu* with the increase in the blood-pressure. The author regards the appearance of the pupil as a very reliable guide for the administration of the chloroform, as by it he is enabled to judge accurately concerning the condition of the patient.—*Medical Record*, August 18, 1888.

Salicylate of Mercury in Syphilis and Gonorrhœa.

Carl Szadek has been studying the effect of salicylate of mercury in syphilis, and publishes a communication on the subject in in the *Monatshefte für prakt. Dermatologie*, No. 10, 1888. He employed the salt internally in 25 cases of syphilis, using the following formula:

℞ Hydrarg. salicylat. . . . . gr. xv
Ext. et pulv. glycyrrhizæ q. s. ut fiant pil. No. lx
Sig. Three to six pills after meals.

The drug never caused any disagreeable gastric or intestinal disturbances. The mouth was carefully attended to, and salivation and stomatitis were never observed, even after the drug had been used a long time. In all cases in which the milder symptoms of secondary syphilis (roseola, mucous patches in the mouth and fauces) were present, the symptoms of the disease affecting the skin and mucous membranes began to disappear in a very few days. Szadek also tried intramuscular injections in 12 cases of recent syphilis, with maculæ and large and small papules, papular angina, etc. For this purpose he employed the mercury suspended in the following way:

℞ Hydrarg. salicylat. . . . . gr. iii
Mucil. acaciæ . . . . . ♏ivss
Aq. destil. . . . . f℥ii
Sig. For injection.

The injections were employed at intervals of two or three days, their number varying between 6 and 12. The pain caused by them was not worth mentioning, nor was the reaction of any significance. After as few as 3 or 5 injections, a decided influence upon the secondary symptoms of the disease was perceptible. In most cases, from 8 to 12 injections sufficed to cause the disappearance of the syphilitic symptoms. As after-treatment, Szadek employed the same salt internally.

He has also employed the salicylate of mercury as an injection for gonorrhœa, using it four or five times a day, according to the following formula:

℞ Hydrarg. salicylat. . . . . gr. iii
Aq. destil. . . . . f℥ viii
Sodii bicarb. . . . . gr. xv–xx
M. Sig. For injection.

As a rule, after three days, there occurred a diminution of the discharge; in from 14 to 21 days, recovery from an acute or subacute attack. At times, however, the drug entirely failed.

Szadek believes that he is justified in drawing the following conclusions as the result of his experiments: 1. The salicylate of mercury is not less active as an antisyphilitic agent than the other mercurial preparations hitherto employed; it is a very suitable preparation in the treatment of secondary syphilis. When employed internally, it soon causes the disappearance of the milder syphilitic symptoms, and is also very useful in the after-treatment. When employed in the form of intramuscular injections, it causes a complete disappearance of the syphilitic symptoms.

2. The drug occasions no disagreeable local symptoms; in this respect it is to be regarded as the best mercurial preparation known as present. 3. External use of the salicylate of mercury is very useful in different syphilitic infiltrations and ulcerations, bringing about their resorption and healing. 4. In acute and subacute gonorrhœa it also acts favorably, but it has no abortive action. *Wiener med. Presse*, July 8, 1888.

Pathology of Bright's Disease.

Gaucher (*Gazette Hebdomadaire*, xxxiv, 4, p. 52, 1888) has sought to prove that the large white kidney may be caused by poisons, not only such as are introduced into the organism, but also such as are formed in the organism itself as the result of incomplete oxidation of albuminoids, which poisons, like leucin, tyrosin, kreatin, and kreatinin, etc., are comprised in the series of extractives. If animals are injected for a long time with these solutions, the clinical and pathological picture of the large white kidney is obtained.

In the healthy human organism, these extractives are very sparingly found; but they increase in diseases of the liver—in cirrhosis of the liver, in icterus gravis, and the albuminuria observed in these diseases is to be referred to a nephritis arising through the accumulation of extractives. Probably this is developed also in other, perhaps in all, chronic diseases, and forms the basis of the albuminuria so frequently observed.

"Excessive ingestion or excessive production of extractives, deficient excretion of the latter, and already existing lesions of the kidney are the usual conditions which determine the development of the large white kidney."

As regards treatment, it follows that, when kidney-disease exists, food-stuffs rich in extractives (meat broth, extracts of meat, etc.) will make the condition worse, and are therefore to be avoided.—*Schmidt's Jahrbücher*, July, 1888.

An Unpremeditated Cæsarean Section.

The town of Titusville, Pa., has been very much excited over an unpremeditated Cæsarean section which was recently performed there by Dr. Varian. It seems that a young woman who was far advanced in pregnancy succeeded in imposing upon the credulity of her physicians to such an extent that she was thought to be suffering with an ovarian tumor. Pregnancy was suspected, but absence of the fœtal heart-sounds, taken in connection with the young woman's positive declarations that she could not be pregnant, led to the mistake in diagnosis. In an operation undertaken for the removal of the supposed tumor, the uterus was opened and a living child, weighing about eight pounds, extracted. Dr. Varian's own account of the case will be published soon.

Professional Courtesy.

One hears so much about the jealousy of physicians—of their mutual backbiting, quarreling, and generally splenetic state toward each other—that it is really somewhat refreshing to learn that we are not in reality a disunited body. Our esteemed contemporary, *The Journalist*, for example, has recently celebrated our united state in the following somewhat ferocious terms:

"There is not in this world to-day a more powerful, more monstrous, more unjust, and iniquitous organization in existence than that mysterious bond which fetters the medical profession as with links of steel, which is known as 'professional courtesy.' Professional courtesy is an excuse for neglect, for procrastination, for carelessness which is in too many cases tantamount to murder. It is no rash statement to assert that there are hundreds of cases known to physicians who are in other respects reputable men, where patients have died through the criminal neglect and stupidity of the attendant physician; yet you could not worm an admission of that sort out of them in a court of law—they are bound by 'professional courtesy' to allow their ignorant incapable fellow-practitioner to go on murdering without a word of remonstrance."

Thus it seems that physicians do stand by each other, after all. This is not very surprising when one considers the difficulties and limitations of our art. When an architect miscalculates in building a bridge, his incompetency can be demonstrated mathematically; but when a chronic invalid, with some obscure malady, receives a series of prescriptions, under which he or she gets no better, the incompetency of the physician is hard to prove. The malady itself may be impossible of recognition and of cure. Doctors know this. It compels them—if they have any sense of justice—to charity toward their fellows. We follow a difficult and laborious calling. There are black sheep everywhere, and sometimes, perhaps, "professional courtesy" has been made to shield them; but we do not think that harm often comes from its exercise, and, indeed, medicine could not be practiced without it.—*Medical Record*, July 21, 1888.

Detection of Traces of Bismuth.

At the meeting of the Paris Society of Pharmacy, July 14, 1888, M. Léger made a communication, illustrated with experiments, on a test for bismuth which he proposes. One of the most sensitive tests for alkaloids, he said, whether they are natural or artificial, is the double iodide of bismuth and potassium. The reaction, it is true, is quite general and reliable, but not very instructive, because it has never helped us so far to form more definite conceptions of the constitution of alkaloids. The idea came to M. Léger to reverse the test, and use an alkaloid to detect bismuth instead of bismuth to show up an alkaloid. He found the reagent very satisfactory in all respects, especially as regards sensitiveness. For obvious reasons, cinchonine was the alkaloid selected. A solution of potassium and cinchonine hydriodate added to a liquor containing 1 per 10,000 of bismuth gave immediately a bright red precipitate; with 1 in 100,000 of water a very appreciable tinge could be observed even from a distance. With 1 in 500,000, a faint hue can with some precautions be recognized. At the same time, care must be taken how the bismuth solution is made; there should be no alcohol, no alkalies, or excess of sulphuric acid. To extend further the usefulness of the test, he tried to use it for quantitative estimations of bismuth, but so far without success, owing to the uncertain composition and keeping-properties of the precipitate. Hence it can only be recommended as a qualitative test for bismuth, but an excellent one. In answer to a query by M. Petit, M. Léger added that mercury could not be mistaken for bismuth with the test in question. While bismuth affords a very bright red precipitate, mercury gives only a faint yellow one, and but little of it. —*Chemist and Druggist*, July 14, 1888.

Two Cases of Gouty Neuritis.

Mr. J. Gurney Carruthers reports two cases of gouty neuritis in the *Lancet*, June 30, 1888. In the first case, a man forty years old, a retired officer of good physique and temperate habits, given to work very hard at chess and music-composing, and not fond of athletic pursuits, was seized, on February 5, with general malaise, some conjunctivitis, intense supra-orbital pain, and intolerance of light. A mixture of iodide of potassium (half a drachm), tincture of colchicum, and bicarbonate of potash was given every four hours. He continued to get worse steadily. On February 7, atropine was applied to the eye, which was now intensely painful and suffused, the conjunctiva being greatly injected, the pupil contracted, and there being intense photophobia. The mixture of iodide of potash was continued. After the dilatation of the pupil, it was seen to be lozenge-shaped, the result of former attacks. Chloral was given at night, with partial success. A dull aching pain was continuous, varied by paroxysms of an acute character at two-hour intervals, and lasting from twenty to thirty minutes; this pain was often relieved by tapping the supra-orbital region lightly with the fingers. A liniment of aconite and chloroform was applied, with partial success, and was continued until February 10, when the upper and inner angle of the cornea showed symptoms of ulceration, which, however, resolved. An ophthalmic surgeon was called in, who recommended the treatment to be continued, and leeches to be applied to the temple, which caused great irritation; hot applications were also advised, with the same result. A blister had been applied to the nape of the neck, but without giving relief. On the 12th, the severe injection of conjunctiva and sclerotic was lessened, perhaps owing to the blister, which was acerrime. The paroxysms were not so frequent, although as severe. The patient was given green iodide of mercury (one-quarter of a grain), in addition to the half-drachm of iodide of potassium; also, a fairly good liquid diet, with two wineglassfuls of whiskey and alkaline water. The paroxysms still continuing, the patient, who is of a highly nervous organization, became rather exhausted; a grain of opium was given, although he declared opium disagreed with him. To counteract the depressing headache caused by the opium, a glass of champagne was given at 11 A.M., and repeated at lunch, the allowance of whiskey still being taken. This state of things continued for four days; the exacerbations of pain became gradually less frequent, the conjunctival injection subsided, and the eye returned to its normal state. The pupil was somewhat lozenge-shaped and the sight defective. There was no photophobia. Tonics were then given. The duration of the case was twenty days. The iodide of potassium was increased to one drachm every four hours, without causing more than turgescence of the pharynx. There was no iodism.

In the second case, a man of intemperate habits had frequent attacks of neuritis, affecting the crural nerves. He used to have intense lightning pains, and severe spasm of the muscles, so acute that he would scream out. A grain of muriate of morphia used to be injected locally, then half a drachm of iodide of potassium given every four hours, until iodism was fully established, which was generally in twenty-four hours, when the pains subsided and the patient became better.

Many authorities, Mr. Carruthers remarks, condemn opium in all gouty conditions; but he sees no objection to it, provided suitable eliminative treatment is also employed. He uses it freely in cases of gout, both acute and chronic.

Why Albinos Do Not See Well.

In the *St. Louis Med. and Surg. Journal*, July, 1888, Dr. A. D. Williams says that the white flaxen hair of albinos shows that there is a deficiency of coloring material in their bodies. Further proof of this fact is found in the absence of the necessary amount of pigment in their eyes. Such persons have "pink" eyes because there is not pigment enough in the iris and upon its posterior surface to prevent the red reflex of the fundus from shining through the iris. Such persons are always greatly annoyed by strong light, because there is not sufficient color to prevent the ingress of a flood of it. It enters not only through the pupil, but through the substance of the iris as well. The choroid being likewise deficient in pigment, the excessive amount of light dazzles and greatly confuses vision. Furthermore, the deficiency of pigment in the choroid prevents the light, after it has properly acted on the retina, from being absorbed, that being the main function of the choroidal pigment. Albinism is an unfortunate condition, as there is no way to supply the deficient pigment to the iris and choroid. The annoyance is somewhat palliated by the use of properly colored glasses. These supply the place of the natural pigment to a slight extent.

Creoline as a Mouth-Wash and Gargle.

Schnitzler recommends (*Internat. klin. Rundschau*, No. 27) creoline in the obstinate form of follicular angina; he applies it with a brush or uses it in an atomizer. The taste is disagreeable. The following formulæ are given:

℞ Creoline . . . . . gr. xv–xxx
Aq. destil. . . . . Oi.
Aq. menth. pip. . . . . ℥iii
M. Sig. Use as a gargle.

℞ Creoline . . . . . gr. xv–lxxv
Aq. destil. . . . . f℥iss–iii
M. S. For local application with brush.

℞ Creoline . . . . . gr. iss–viiss
Acidi borici . . . . . ℥iiss
Ol. menth. pip. . . . . gtt. xx
M. Sig. For insufflation.

—*Deutsche med. Wochenschrift*, Aug. 16, 1888

Antiseptic Precautions in Internal Urethrotomy.

At the meeting of the Harveian Society of London, May 17, 1888, Mr. Bruce Clarke read a paper on the "Value of Antiseptic Precautions in Internal Urethrotomy." Attention was drawn to the fact that this operation had been advocated for many years in certain cases of stricture which do not yield readily to dilatation, yet its principles had never been generally accepted by surgeons. He thought this was due partly to the fact that its results were not supposed to be good, and partly to the dangers of the operation itself. As to its results, he said it was often urged that the worst strictures were always those in which urethrotomy had been performed. Of course this was perfectly true, but it would be fairer to state that it was only the worst strictures that were submitted to urethrotomy. If strictures were neglected after the operation, they, of course, recurred, and this gave a certain currency to the idea that it was the internal urethrotomy that had made them relapse. The dangers of the operation, he said, were dependent upon septic fever, and this depended upon either self-infection from a septic urethra or on dirty instruments. The latter source of infection could be easily guarded against by the thorough cleansing of instruments and catheters, whilst the purification of the urethra was no easy matter. To effect this, however, as far as possible, the urethra should be irrigated with sublimate (1 in 2000) for several days beforehand, and, upon the stricture having been divided, the bladder should be washed out with a similar solution, and then with hot water at a temperature of 105° F. Afterward, a catheter should be tied in for twenty-four hours. By this means the urine came very little into contact with the urethra, and septic infection was avoided. Fifteen cases were related in which the plan had been successfully tried by the author, and he alluded to some in which the plan had been suggested to other surgeons.

Mr. Swinford Edwards, in discussing Mr. Clarke's paper, said that in the last six internal urethrotomies which he had performed he had not only carried out the suggestions of Mr. Bruce Clarke, but had administered boracic acid before the operation, and for a few days after, with a view of sterilizing the urine, as suggested by Dr. Palmer. In none of these cases did urinary fever supervene; but, brilliant as was internal urethrotomy, he believed that the time was soon coming when it would be almost, if not entirely, supplanted by electrolysis for strictures in the deep or fixed urethra which were unfitted for the simple treatment by dilatation.—*Lancet*, July 14, 1888.

Arsenic in Textile Fabrics.

F. E. Matthews, an English chemist, writes to the London *Daily News* that, having traced several cases of arsenic-poisoning to cretonnes and like fabrics used as curtains, etc., he undertook an extended examination of these fabrics. Forty-four samples of cretonne have been analyzed by him, and of these none was found absolutely free from arsenic. Three contained only the faintest trace, 21 contained distinct traces, and, in the remaining samples, arsenic was present in poisonous quantities. In his analyses, he has grouped 11 of them as "very bad," and the other nine are bad and distinctly dangerous. One of the worst specimens has been examined quantitatively, and yielded an amount of arsenic equivalent to rather more than 19½ grains of arsenious oxide per square yard. It is quite a common occurrence to have enough of these fabrics in a room to contain, at this rate, sufficient arsenic to give 100 people a fatal dose. As far as the analyses have gone at present, they do not show that any one color is more poisonous than another, as, strange to say, the greens and blues, that would be first suspected, have until now proved purer than reds, browns, and blacks. In the case of imitation Indian muslin, only five samples have been analyzed, but they all contained arsenic in poisonous quantities.—*Druggists Circular*, July, 1888.

Creasote Capsules.

Creasote put up in gelatin capsules soon destroys the container, and for this reason only a few should be put up at a time. Groh, of Vienna, after a number of experiments, has found that, when the creasote is rubbed up with cacao powder, it will not only not attack either a gelatin container or a wafer, but is much better borne by the stomach. Capsules or wafers thus put up do not become soft, even after long standing, nor do they give forth that peculiar disagreeable odor of creasote, which is so offensive to some persons.—*National Druggist*, August 15, 1888.

Native Indian Obstetrics.

From a report of Dr. Keegan, Presidency Surgeon of Lahore, says the *Medical Press and Circular*, July 11, 1888, some estimate may be formed of the immense boon conferred upon the women of India by Lady Dufferin's movement to supply them with medical aid in child-birth. The method of conducting labors throughout Central India only a year or two ago was as follows: The native midwives, or *dhaies*, on being called to a woman in labor, hasten delivery as much as they possibly can by exerting pressure on the abdomen; they have no idea of waiting upon nature. The child being born, the mother is made to stand up, and pressure is again applied to the woman's abdomen, by means of the head or bent knee of the *dhaie*. A bandage is then passed round the woman's abdomen, and she is then allowed to lie down on a charpoy, under which a charcoal fire is placed, which causes the room to become excessively warm. The room selected for the confinement is usually in the very interior of the house, and may be described almost as an hermetically sealed chamber. The day succeeding the birth of the child, the mother is subject to fumigation, which is continued for about twelve days, and at the same time indigenous stimulating condiments are given, which are supposed to give milk in abundance. These condiments are used four or six weeks. The mother is allowed to drink nothing but warm water from the first ten days. In the hot season of the year, the charcoal fire is used both day and night for the first twelve days succeeding the birth of the child. Subsequently it is used from evening to early morning, and is not discontinued *in toto* until the expiration of a month or six weeks. During these six weeks, the child is subjected to the same atmospheric conditions as the mother, and, whenever it cries, more fuel is added to the fire, and the child soon ceases to cry, owing to the effects of the carbonic acid gas. Dr. Keegan adds that this method of conducting confinements is, with some slight modifications, more or less prevalent throughout the greater portion of India.

Good Advice.

The editor of the *Alienist and Neurologist* gives the following good advice: "Take care of your loved ones at home, brother doctor, and, as you love them, so will you feel your duty fairly to the world without. But you cannot give the outside world all, and give your family a part; and, if you give it all, the world's charity will not recompense your sacrifice by any exuberant providence for your uncared-for loved ones. This does not apply if you are an inveterate bachelor, a eunuch, or a monk; but it does apply with more force than our feeble words have expressed it, to many a faithful doctor whom we know, and to many more whom we knew in our youth, but who have long since gone to the reward of the faithful to duty, in heaven, who might have staid longer on the earth to brighten it, had they been just a little more selfish for themselves and their own, and a little less completely self-sacrificing to all the world but self and home."

Mechanism and Treatment of Pneumonia.

Dr. W. C. Van Bibber, in a paper on the mechanism and treatment of pneumonia, read before the American Medical Association, May 8, 1888 (*Journal Am. Med. Assoc.*, July 28, 1888), states his conclusions in the following propositions:

1. The mechanical interference to the circulation and aeration of the blood in the lungs is the main symptom to be combated in the treatment of pneumonia.

2. It requires prompt, urgent, and aggressive treatment in the earlier stages of the disease, and this mechanical relief can be afforded by decided local depletion.

3. Even after the effusion into the parenchyma has occurred, it requires still further local depletion to preserve the heart and keep open the circulation in the roots of the lungs.

4. Pneumonia admits of study by mechanical as well as vital principles, and its pathology may be elucidated and its treatment improved by study in these directions.

NEWS.

—London is to have an *Illustrated Medical News*.

—Yellow fever is said to have broken out among Jacksonville refugees at Hendersonville, N. C.

—Basket collections are to be taken up in some of the churches of Camden, N. J., in aid of the yellow fever sufferers.

—The health reports of New York City continue to show an unusual number of cases of diphtheria, scarlet fever, and measles.

—Professor Proctor, the well-known astronomer, died in New York City, September 12, of yellow fever, which he contracted while in Florida.

—In a "youngest grandparent" contest, Chapel Hill, North Carolina, leads with a negro woman who had a granddaughter, it is asserted, at the age of 28.

—The *Maryland Medical Journal*, September 15, 1888, states that the meeting of the Southern Surgical and Gynecological Association, which was announced for September 11, 12, and 13, was postponed on account of the quarantine laws.

—The *Boston Medical and Surgical Journal*, September 13, 1888, says that Dr. Samuel O. Vanderpoel, of New York, has been sued by a hotel proprietor of Rhode Island for making a diagnosis of scarlet fever in the case of a child sick at his hotel, by which the plaintiff's business was damaged. There were good grounds for the diagnosis.

—The *Lancet*, August 25, 1888, says: A French medical man recently prescribed one gramme of sulphate of atropine instead of a centigramme, the error resulting in the death of his unfortunate patient. The doctor and the chemist who dispensed the prescription have been found guilty of homicide through imprudence, and the former was condemned to pay 600 francs as compensation, and the latter to five day's imprisonment and the payment of 400 francs.

—Boston papers tell of "the singular death, at Danvers, of Miss Emma Felch. She was taken ill some months ago, and, from the fact that her mother died of cancer, she became possessed with the idea that her sickness was from the same cause. Her physicians could find no indication of cancer, but she asserted that she had one, and located it. She refused food, saying it distressed her. At her desire, after she died, an autopsy was held, and no cancer could be found. It was decided that her disease was purely sympathetic."

HUMOR.

Just What He Wanted.—Barber (desirous to please): "How would you like your hair cut, sir?" Customer (innocently): "First-rate. That's what I came in here for."—*Idea.*

Collector (on his tenth visit)—"Look a-here; how many more times do you want me to call with this little account?" Bill Overdue—"Why, man, I don't care if you never call again."

Smith: "What has become of Dr. Cure-all?" Jones: "The man who advertised to cure every complaint under the sun?" Smith: "Yes." Jones: "Oh, he died the other day from a complication of diseases."

"Stewardess, Stewardess!" screamed the old lady in a storm, "my room is flooded; do, please, ask the captain to rent me one of those water-tight compartments. I declare, this is perfectly dreadful."—*Ocean.*

A Farmer in Western New York declares that he saw a ghost eating green apples in his orchard the other night. Now, if a case of cholera in phantom in Western New York be heard of, we shall know what caused it.

A Wrong Diagnosis.—"You are evidently worried over business matters," diagnosed a young physician. "What you need is peace of mind." "My dear sir," replied the patient, "I get a piece of mind every day."—*Epoch.*

Had a Hard Night.—Caller—"Your little dog doesn't look very well this morning, Mrs. Hobson." Mrs. Hobson—"No, poor little fellow! The baby's crying kept him awake all night. He barked until nearly morning."

At the Police Court.—The judge questioning a witness: "Your name?" "Josephus Horther." "Your age?" "Forty-three." "Your profession?" "Dramatic author." "That is not a profession—it is a disease."—*Truth.*

OBITUARY.

JOHN WOOLVERTON, M.D.

Dr. John Woolverton, Ex-Mayor of Trenton, died September 14, 1888. He was born in Hunterdon County, October 27, 1825. He studied at Lafayette College, and was graduated in medicine from the University of Pennsylvania. He was prominent in politics and in the Masonic fraternity.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D.

DETROIT COLLEGE OF MEDICINE.

SESSION 1888-89.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S, and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, September 26, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins March 27th, 1889, and closes June 17th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,

33 Lafayette Ave., Detroit, Mich.

University of Pennsylvania

MEDICAL DEPARTMENT

The 123d ANNUAL WINTER SESSION will begin Monday, Oct. 1st, at 12 M., and continue 7 months.

The PRELIMINARY SESSION begins Monday, September 17th, the SPRING TERM Monday, May 6th, 1889.

The Curriculum is graded, and three annual Winter Sessions are required. Practical instruction, including laboratory-work in Chemistry, Histology, Osteology, and Pathology, with Bedside Instruction in Medicine, Surgery, and Gynæcology are a part of the regular course and without additional expense.

For catalogue and announcement containing particulars, apply to DR. JAMES TYSON, Sec'y, 36th and Woodland Ave., Phila.

W. H. WALMSLEY & CO.

SUCCESSORS TO R. & J. BECK,

Manufacturing Opticians,

No. 1016 Chestnut Street, Philadelphia, Pa.

Microscopes,

Microscope Accessories,

Mounting Materials,

Dissecting Instruments,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Western Pennsylvania Medical College,

City of Pittsburgh.

The *Regular Session* begins on the last Tuesday of September and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation.

A three years' graded course is also provided. The *Spring Session* embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects: this session begins the Second Tuesday in April and continues ten weeks.

The laboratories are open during the collegiate year for instruction in Chemistry, Microscopy, practical demonstrations in Medical and Surgical Pathology, and lessons in Normal Histology.

Special importance attaches to the superior clinical advantages possessed by this college. For particulars, see annual announcements and catalogue, for which address the Secretary, Prof. W. J. ASDALE, 2107 Penn. Avenue, Pittsburgh.

NOW IT IS A

Zentmayer Binocular Microscope.

2 EYE-PIECES. 2 OBJECTIVES. (8-10 and 1-5.)
THE REGULAR "HISTOLOGICAL" STAND.

In good order. Can be used as a Monocular or Binocular—either. **$50 will buy it.**

Will be sent by express without extra charge.

NERVOUS APHONIA CURED BY THE LOCAL USE OF COCAINE.

BY J. E. SCHADLE, M.D.,
ST. PAUL, MINN.

Sometime during the month of August, 1886, Mary L., fifteen years old, in company with her father, presented herself at my office for advice regarding loss of voice, which had taken place three months previously.

Phonation, as well as whispering, was sometimes impossible. About two years before the present trouble came on she was afflicted in a similar way, the aphonia on this first occasion having lasted several months. During this attack, treatment, consisting of various neurotic remedies, prescribed with a view to re-establish the voice, had been tried by the family physician, but no perceptible benefit accrued from it, and the case was finally allowed to go on untreated for an indefinite time. One day, in the midst of a violent fit of laughing, audible tones were uttered by the patient, which were almost immediately followed by a full return of the voice.

Apart from occasional hoarseness and more or less huskiness, vocalization remained unimpaired until the seizure in which I was consulted began. As to the hoarseness, it was of long standing, and figured as an annoying symptom long before aphonia was manifest. It seemed, too, to be getting worse as the young woman grew older.

In her general appearance, she presented a well-developed organization. At the age of thirteen, menstruation began, the periods occurring at regular intervals, and without being attended by influences calculated to derange the function.

As far as specific or tuberculous constitutional diseases were concerned, the family history was characterized by the absence of them. It was apparent, however, that, from her mother, a nervous temperament had been inherited, for excitement of an emotional character usually tended toward superinducing hysterical phenomena in the mother. These nervous peculiarities were strongly marked in the daughter.

Aside from complaining of loss of voice, there were evident signs pointing conspicuously to the existence of catarrhal conditions of the nasal tissues, producing, as it appeared, a great deal of discomfort.

The morbid action was not confined only to the mucous membrane of these parts, but cough and a dry and irritable sensation in the pharynx and larynx distinctly showed that these organs were also implicated in the same pathological change.

Among other subjective symptoms, were a feeling of intra-nasal pressure, and lancinating pains over the bridge of the nose, which invariably became quite pronounced during the height of acute rhinitis, for which she had a peculiar susceptibility, the slightest exposure to either draughts of cold air or dampness usually occasioning it.

A muco-purulent discharge coming from both the anterior and the posterior nares formed a troublesome condition, of which much complaint was made.

The unpleasant disturbances induced by

these acrid secretions from the nasal chambers were characterized by unsightly excoriations of the margins of the nostrils and of the upper lip. The presence of the discharge posteriorly kept up a constant desire to "hawk and spit," accompanied by nausea and sometimes actual vomiting. There was, too, digestive derangement, which was indicated by a heavily coated tongue, flatulence, and acid eructations from the stomach.

Examination of the nasal fossæ by reflected light showed hypertrophy of the middle, and atrophic changes of the inferior, turbinated bones, the mucous membrane investing these and associated structures varying very much in its abnormal appearances. That covering the middle turbinated region was congested and thickened, whilst the membrane lining the inferior region was purple, smooth, and glazed, and seemed divested of its ciliated epithelium.

The larynx and vocal cords, upon a laryngoscopic examination, were found to be in a state of chronic congestion.

Besides the hyperæmic appearance of the vocal cords, attempted phonation, as seen by the mirror, failed totally in approximating them, thus showing the marked functional inactivity of the larynx.

The treatment, therefore, of this interesting case naturally resolved itself into the institution of remedies calculated to restore the voice as speedily as possible and to remove the catarrhal products of the nose and throat.

As cocaine comprised such a wide therapeutic range in controlling local affections of nervous origin, the idea occurred to me that it might serve a valuable purpose in effecting an immediate restoration of the voice. Consequently I made an application to the larynx with pledgets of cotton saturated in a four per cent. solution of the drug. After allowing sufficient time for local anæsthesia to take place, I asked her to say "Yes." She did so, audibly and distinctly. "No" and other monosyllabic words were spoken in rapid succession. Suffice it to say, that before leaving the operating chair, she was enabled to converse aloud without difficulty. The father who sat by observing the manipulations was amazed to see the phenomenal effect of the medicine, and he seemed overcome with gratitude for what was done for his child.

Two days afterward, a second visit was made and the voice was still good, the interval having been passed by occasional singing and considerable talking.

Treatment of the catarrhal symptoms improved the strength and purity of the voice.

Nowhere in the extensive literature of cocaine do I find this use of the alkaloid stated, and I believe I herewith record for the first time an observation in the local treatment of nervous aphonia which is invaluable and should be recognized by those who see these cases.

Galvanism we know has been our best remedy, but, when we take into consideration how tedious and troublesome its use becomes, especially when the applications are made directly to the laryngeal cavity, we should welcome with delight another local agent whose application is effected without any trouble whatsoever.

The *modus operandi* of the cocaine as it was used in this case, I presume, consisted in allaying peripheral nervous sensibility of the mucous membrane, and subduing thereby muscular irritability of the larynx. The larynx under these circumstances is placed, so to speak, in splints by the anæsthesia, thus overcoming active antagonism of the abductors and allowing the apparently paralyzed adductors to regain their natural tone and activity. The vocal cords can then be approximated and made tense, which is followed by voice production when phonation is attempted.

Under local treatment for a period of three months the pharyngo-nasal catarrh was cured.

The use of the electro-cautery reduced the redundant tissue of the middle turbinated bones, which was followed by a subsidence of intra-nasal pressure and the neuralgic pains that radiated from the bridge of the nose.

The atrophic changes of the inferior bone were arrested in their progress by a systematic employment of cleansing and stimulating agents. The post-nasal space, the pharynx, and the larynx were treated with local and constitutional alterative remedies, consisting principally of the iodine group.

This case illustrates conclusively, I believe, that, in one nervously predisposed, an exciting cause of aphonia may not unfrequently be found in a catarrhaly diseased state of the mucous membrane clothing the pharyngo-nasal cavities or the larynx. It, moreover, demonstrates the importance of properly and thoroughly interrogating these organs when such cases present themselves.

104 East Third Street.

SUPPURATIVE TONSILLITIS, WITH PASSAGE OF PUS INTO MEDIASTINUM AND PLEURA; DEATH.

BY JOHN J. REID, M.D.,
SURGEON TO CHARITY HOSPITAL, NEW YORK.

The interest of this case rested not so much on its rarity as on the difficulty of diagnosis. When he was admitted there were none of the common and significant signs usually found in quinsy, but there were evidences of cellulitis around the lower jaw and extending below the chin, not unlike what is noticed as a result of ulcerated teeth.

The history of the case was as follows: John Jenkins, German, 27 years old, entered hospital June 20, 1888. Note taken then states: Patient cannot speak sufficiently plain to give an intelligent history. By means of an interpreter it was inferred that a swelling of the neck and face was noticed a week before his admission to the ward. The swelling was on the left side, but rapidly spread to the right. On admission, this was not noticed in any decided manner, but there was a swelling in the vicinity of the lower jaw which, in connection with the existence of ulcerated teeth, gave rise to the supposition that the diseased teeth were the cause of the cellulitis.

July 21, an incision was carried down alongside of the suspected tooth, but no result followed beyond free hemorrhage, which had to be controlled with pressure. Temperature, 104 1-7°; pulse, 120.

July 22. No improvement. The swelling is now most marked below the jaw, and an exploring needle was inserted, but without yielding any sign of pus. Has to be fed by the rectum, from inability to open the jaws.

June 23. The patient sank rapidly and died. Before death the tissues of the neck became emphysematous.

Autopsy.—An incision was made in the median line of the neck and extended laterally on each side from the chin. The sublingual and the other gland in the vicinity were purulent, and on passing backward abscesses were found in both tonsils, but more particularly in the left, which had broken down and permitted the pus to escape into the tissues of the neck, the pus following down the course of the deep fascia into the mediastinum. The pus was found in the left pleural cavity and over the pleura of the left lung.

RESULTS OF NEPHRO-LITHOTOMY AND NEPHRECTOMY.

BY CHARLES BAUM, M.D.,
PHILADELPHIA.

Nephro-lithotomy.

The first premeditated incision through the sound tissues into a kidney, for the removal of a contained calculus, was successfully performed by Henry Morris, of London, England, in 1880.

The operation was named nephro-lithotomy, and, under this term, he intended to designate the "cutting a stone out of a kidney, which, so far as can be ascertained by clinical examination, is not dilated or otherwise altered in form; and which, but for the presence of the stone, is presumably healthy."

From the time of Hippocrates downward, upon the appearance of external swelling or abscess in the loin, connected with renal suppuration and calculus, incision and an attempt to extract the stone were properly sanctioned. Surgeons, even from the earliest period, have been ready to follow and enlarge a sinus communicating with a renal calculus, and thus effect its removal; but to cut down upon an undilated kidney, early in the course of the disease and before any great disorganization has occurred, was hardly deemed feasible by men of great learning and experience. This Morris accomplished.

At the present time, most surgeons have extended the original definition of nephro-lithotomy so as to embrace cases in which there even may be some slight external fulness in the loin, yet not the pointing of an abscess, but in which the renal tissues have not ruptured.

Having recently conversed with an experienced general practitioner of medicine in regard to the operations of nephro-lithotomy and nephrectomy, it was a somewhat difficult task to convince him of the success attained. As memory is not able to retain accounts of various operations for any great length of time, a number of unselected cases have been arranged in chronological order in the appended tables, which, it is hoped, may supply the evidence demanded.

In the nephro-lithotomy table, no case has been cited in which a sinus led down to or penetrated the kidney, or in which the operator failed to detect a stone after reaching the gland. A considerable number of such exploratory operations have been performed, resulting frequently in complete relief of the symptoms, and rarely with fatal results.

Except where otherwise mentioned, all incisions were made in the loin.

Cases of Nephro-lithotomy.

No.	Reference.	Date of Operation.	Operator.	Sex and Age.	Description of Calculus.	Result		Remarks.

Combined abdominal and lumbar,	2	"	
Lateral, ...	1	"	1 " (No. 24).
	50	"	8 "

In case No. 5, the pronounced symptoms had lasted only four weeks, and at the time of operation there was some fulness in the loin, while at the autopsy the kidney was found to be disorganized. To learn the condition of both kidneys, Mr. Thornton twice opened the abdomen of the same woman, by Langenbuch's incision, operating the second time after an interval of two years, and then immediately cut through the loin to extract the calculus, the patient recovering (Nos. 11 and 23). The sad mutilated condition of the woman (No. 32), when she presented herself to Carter and Paul, comes with a warning note to abdominal surgeons. She had submitted to the removal of normal ovaries at separate operations by other surgeons, with the hope of securing relief from pain, which, happily, was afforded by the removal of a calculus from her kidney. In a medico-legal and moral aspect, this case is almost unique. Incessant emesis followed the attempt to arrest hemorrhage by packing the kidney with antiseptic gauze moistened with a "weak solution of carbolic acid" (No. 47), and only ceased when the packing was removed on the third day. The condition was attributed to renal reflex.

Finally, nephro-lithotomy saves the sufferer having renal calculus from great and often long exhausting pain, from suppuration and consequent disorganization of the kidney, from the more serious operation of nephrectomy, and, in some cases, from direct death.

Nephrectomy.

Not more than a score of years ago, nephrectomy was considered an operation to be carefully shunned. As the result of errors of diagnosis, the operation had been performed a few times, always by abdominal section.

To Gustav Simon, of Heidelberg, belongs the honor of devising and successfully executing the first premeditated nephrectomy, and of introducing the method of operation through the loin.

Congenital absence of a kidney had been observed in the post-mortem room. Experiments on living animals had shown the ability of the system to accommodate itself to the loss of one kidney, and, upon killing the animals, the remaining kidney was found to have increased considerably in size. It became evident, therefore, that one kidney of normal structure could continue life in apparent health. In many cases demanding nephrectomy, the remaining healthy kidney undergoes by degrees a physiological

hypertrophy, in proportion to the disability of its fellow, so that, by the time the operation is performed, it is equal to the demands made upon it The same ability has been observed after the removal of one gland, necessitated by a wound.

The following table of unselected cases of nephrectomy is arranged chronologically and does not include any case published by Dr. Robert P. Harris (*American Jour. Med. Sci.*, July, 1882), by Prof. S. W. Gross (*Ibid.*, July, 1885), by Dr. J. Homans (*Boston Med. and Surg. Jour.*, 1884, cx), or by me (*Phila. Med. Times*, Feb. 21, 1885).

Under the column of "form of incision," the lumbar operation is indicated by L, the median abdominal by A, and the lateral abdominal, or Langenbuch's incision, by A ("L").

SUMMARY of 63 cases, 44 recovered and 19 died, or 30.16 per cent. Of 57 cases, in which the sex was mentioned, 17 were males and 40 females. Of 57 cases, in which the form of incision was stated, there were 34 lumbar operations; 25 recovered and 9 died, or 26.47 per cent. Among the lumbar operations, 2 were modified by enlarging the wound by T incision, with 1 death; twenty were by abdominal section, 16 recovered and 4 died, or 20 per cent. Among the abdominal sections, 11 were performed in the median line, with 2 deaths; 8 by Langenbüch's incision, with 2 deaths; and 1 by T enlargement of median incision, which recovered. In addition, there were 3 cases in which the abdomen was opened to learn the condition of both kidneys, and immediately the lumbar operation done to extract the faulty kidney; all died.

When we reflect upon the severity of the operation of nephrectomy and the greatly exhausted condition to which many patients had been reduced before seeking relief thereby, and the fact that almost all the cases tended to a more or less early death, the operation fully commends itself to all, because thereby the degree of human suffering has been lessened and life with comfort extended. As in the history of ovariotomy, by an earlier resort to the operation and with greater skill and more perfected methods of operating, the mortality, no doubt, will be markedly reduced.

THE PREVENTION OF CONCEPTION.

BY W. R. D. BLACKWOOD, M.D.,
PHILADELPHIA.

The editorial under this heading in the REPORTER for the 15th inst. has drawn attention to a matter of vast importance to the profession and general public alike. The subject of the regulation or control of conception in the human female has been almost tabooed by physicians partly from indifference, but largely from absolute cowardice in those capable of writing intelligently about it. Although I have read a good deal on the subject in medical and secular journals, the writers were always on one side —they decried the effort to prevent conception. Most authors based their beliefs (for they did not really argue the point) on the religious or moral aspect of this subject, laying special stress on the latter point, and I hold that it is largely because they were afraid of public opinion that they took this ground. All physicians know something of the prevalence of criminal abortion in any community, but particularly in large cities. Every practitioner of extended experience is aware of the ruined physical health of many women because of their practicing criminal feticide, and gynecologists reap their greater harvest from the uterine maladies engendered by instrumental abortions and the results of frequently repeated confinements at close intervals, with the inevitable accidents and concomitant injuries to the uterus under such conditions. How then can we be indifferent to all the suffering thus endured, and how can we evade our plain duty in the problem of preventing, so far as we properly may, the actual distress borne by innocent yet patient and confiding women, together with the inevitable misery and pauperism consequent upon the hordes of children thrown upon the cold charity of the world, when their parents either cannot or will not provide for them? It is all well enough to talk of the enormous death-rate which keeps the population in check so far as its too extended increase is concerned, but the plain answer to this quibble is that the mortality is decreasing perceptibly, I think partly through the restriction of conception, and much of the mortality, especially amongst infants, is due to the fact of their wretched surroundings, to say nothing about their want of stamina from defective intra-uterine development, owing to the poverty of their parents, whose social and pecuniary condition proclaims them as unfit progenitors of healthy offspring. These children should never have been born.

I don't wish to be misunderstood—no one has a more decided belief of the criminality of feticide than myself. I hold an abortionist to be a murderer not alone of the body, but it may be the destroyer of a soul in addition, the child dying before its birth, and I hold him or her equally culpable before the law of God or man, no matter how early he or she interferes to interrupt or to terminate gestation *after conception has occurred*—no matter what the plea may be on the part of the mother or the father of the unborn child, provided the conception is a normal one. So decided are my views as to this matter that I have always refused to perform craniotomy on my own account or to assist in doing so in the practice of others. Fortunately during my obstetrical career, which is now virtually finished (my practice in electrotherapeutics taking up most of my time), I had occasion only once to operate in a presumedly proper case, and despite my associates' protests I did abdominal section and saved both lives. One exception I recognize to this rule, and one only—that of extra-uterine pregnancy when diagnosed so far as may be prior to six weeks, and before rupture of the tube or sac has happened—then I believe and strongly urge electrolysis as the proper method of saving the mother from almost certain death, in the event of which of course the embryo is also lost. As to whether the fœtus should be removed after development of the placenta by laparotomy or be left to nature, I say nothing; others better able to decide than myself will no doubt settle the matter satisfactorily before long.

With a full sense of the importance in all its bearings what I now say, and recog-

nizing clearly just how prompt many physicians will be to condemn me for my opinion (to say nothing about the anathemas of the church in its every faction) I state my belief honestly and fearlessly, that under proper conditions the PREVENTION of conception is not only proper *per se*, but that *it is imperatively demanded under certain circumstances*. Where is the justice of condemning children to inherited syphilis, scrofula, or tuberculosis? Do we know for a certainty that the progeny of the husband or wife afflicted with these or other transmissible maladies will be healthy offspring, their parents being sufferers from them undeniably through inheritance themselves? What right has an epileptic to bequeath his disease to an innocent child, or why should hypocritical sanctimoniousness encourage the multiplication of imbeciles through the mating of men and women who are more or less mentally weak or absolutely insane? It will be said, of course, that continence should govern such people, for marry they will; that the object of the holy state of matrimony is not the gratification of sensual appetites; that the whole outcome and possibilities of conjugal love are in the hands of a higher power than ours; that interference with nature's processes is morally and physically wrong—all of which I unhesitatingly deny as arrant nonsense on a par with the assumption that the marriage bed becomes a brothel when any attempt at prevention or ordinary cleanliness is observed. Ablution does not constitute a brothel, nor is a married woman a prostitute because she practices it. The oft-quoted story also of Onan has, to my mind, no bearing on the question, even were it literally true, which would be hard to prove, except to those who believe all Scripture as meaning precisely what it says, no matter how self-contradictory the narration may be. Turning to the purely medical aspect of the problem, I never saw a more ludicrous display of double cunning than appeared in a medical journal, wherein a professor of gynæcology warned his class against the wickedness and baneful effect of simple aqueous or medicated vaginal douches when employed as a preventive measure after coition, when in the same journal farther on this man begged his pupils not to forget his repeated injunction as to the value of just such injections in large quantity under all conditions of uterine excitement, engorgement, or inflammation. One talk was for the religious public, the other a genuine piece of advice to his students, and a good one as we all know. The carnal demands of man throw aside all recognition of such regulations, and for one husband, who out of regard for the feeling and welfare of his wife abstains from sexual intercourse when it is desirable or absolutely necessary to do so, a million will insist on their "rights" and leave their spouse to endure the consequences.

More than one nation has from time immemorial destroyed the puny and deformed at their birth, so that their people might be strong and brave. This summary method to some extent served its purpose so far as the children were concerned, but it did not save the mothers from the untold suffering dependent upon the absence of intelligent medical advice, in spite of the assumption that savages do not suffer in parturition. To be sure the comfort or happiness of the women in these tribes was not counted, for they were mere chattels or conveniences amongst barbarians. How much better off are many of our civilized communities to-day in this respect? They are not as well off, for, because infanticide is a crime and is not practiced, the maimed, the halt, and the blind are compelled to struggle through life so long as it lasts, and our asylums, almshouses, jails, rookeries, and palaces bear irrefutable testimony that something is wrong, despite the progress of civilization, and the sermons of those who assume to be leaders in medicine or religion. Only last week an estimable lady told me that believing that she would die in the event of having to endure another pregnancy and confinement, her husband was compelled to abstain from sexual intercourse with her, and this because she firmly assured him that she would commit suicide before again undergoing what I am sure was almost martyrdom. Now this man is by nature unable to control his animal passion, and that he gratifies it away from his home is known to his wife. Is it a sin to control conception here (for the woman admits that she is not at all cold or apathetic conjugally) It will not do to say that a man *can* control his sexual appetite, and that he *must* do it. Some men cannot, and many who are supposed to do so are simply apt in concealing their indulgence from public gaze. I could multiply examples of this nature, and so can any physician who has enjoyed the confidence of as many families as I have done for more than a quarter of a century. Shut your eyes as you may, every observant person of intelligence knows my statement to be true.

The reports of lunatic asylums show that unbridled sexual indulgence is a factor in producing mental disorders, and it is equally certain that undue restraint of a natural and necessary exercise of the sexual instinct is likewise a prominent cause of insanity. If prostitution—a gigantic evil—is ever to be eradicated, it can only be done by encouraging judicious marriage relations; and as law and custom have recognized or prescribed monogamy as the proper form of married life with us; and as it is a fact that the male is ever ready and generally solicitous for intercourse during his prime, whilst the female is only so at periodical intervals when at all, at which time she is more exposed to conception than in the interim, it is evident that unrestrained indulgence must lead to rapidly recurring pregnancies in women during the child-bearing period provided they are not sterile. This being so the question is reduced to this—Is it proper, is it humane, is it desirable that the lot of a married female should be a continual round of impregnation, delivery, and lactation? Would such conduce to the happiness of the home; to the welfare of the family; to the sturdiness of the progeny thus generated? I do not hesitate for an instant to say NO! and I look with more than suspicion on the fulminations of those who, assuming superior virtue, condemn any and all attempts to control conception—I don't believe what they say! The land is full of wretched, broken-down women to-day whose lives have been wrecked because they have become mere machines for the reproduction of the race, and if the race is degenerating as many think it is, it is worth careful consideration whether or not something in the way of controlling the quantity would not enhance the quality of the product. Volumes of sounding words might be written on this theme, but in what I have said in this paper my object has been to take the matter plainly in hand, and give a straightforward statement of what I believe to be right and proper in considering a momentous question. To me the matter reduces itself to a choice between fœticide and prevention. The one is an indefensible crime—the other a necessity.

246 North Twentieth Street.

—One hundred and sixty-three new cases of yellow fever and six deaths were reported in Jacksonville September 22. Of the new cases, 103 were among the colored population.

THE PSYCHOLOGICAL INFLUENCE OF ERRORS OF REFRACTION AND OF THEIR CORRECTION.

BY GEORGE M. GOULD, M.D.,
PHILADELPHIA.

The fact indicated by the title above is one that I have repeatedly observed, and yet I have never so much as seen it alluded to in the most distant way by ophthalmic surgeons. It is now a matter of common knowledge that the pathological relations of the eye and the rest of the system are of the most intimate nature; that refractive errors or muscular insufficiencies are the great prolific sources of headache, and that gastric troubles, and numerous forms of reflex neuroses, even chorea and more profound derangements of the nervous system, may ultimately be due to eye-strain. But no one seems to have thought what a tremendous influence upon character and life may be exerted by an uncorrected eye-strain. The microscopic size of the defect has served to keep it ignored, and its influence also minimized by the general ignorance of the extent and exceeding intimacy of relation of the organ of sight and the organ of mind. Indeed, so thorough-going and wide-spread and causal are these relations that the reach of all the other senses combined is but a fraction of that of vision in the creation of intellect. In the light of evolution and psychology, reason and mind may almost be said to be products of the visual mechanism. Language itself, the *sine qua non* of intellect and civilization, is but the record of things seen; the letters of the alphabet are each and all but conventionalized pictographs, and mental pictures, or signs of pictures, are the counters used by the mind in all the processes of logic or thought. The ocular mechanism is like a bank at which mental counters and notes are tested and cashed with the coin of reality and truth. What more natural, therefore, than that a disorganized and faulty bank should disarrange the processes dependent upon it. If a false image, or one that is distorted, or one that is only reached by an exhausting expenditure of energy is the model of comparison, the action of the mind is disturbed, heredity is at war with reality, and the mental mechanism undergoes a subtile but profound change. It is, of course, in the young that this unfortunate process goes on at the most rapid rate, but is all the less noticed by parent or teacher. The most frequent method in which an

uncorrected eye-strain acts disastrously upon the developing mind is in making study and literary labor so irksome that the mind is slowly but irrevocably turned from intellectual pursuits and directed to physical activities for an outlet of its energy. This, in the formative period of the child and youth, is of the most absolute and tragical importance.

A year ago a boy of nine years was brought to me for examination of the eyes. He was a child of large brain, active mind, and fine character, whose parents were educated, intellectual people. But *this boy had never learned his letters.* It had been utterly impossible for him to exercise his accommodation long enough upon a printed page to learn the alphabet. I corrected his hyperopic astigmatism, and within the past year he has more than made up for lost time; in reading, arithmetic, writing, and such studies being well ahead of children of his age. The gist of the matter consists in the question, What would have been the result if this boy's parents had not been keen-witted enough to suspect ocular trouble? Plainly, the boy would have grown up with the poorest interest in intellectual pursuits, and more and more unconsciously driven to physical ones; a professional life would not have been chosen, and the position for which, by all the laws of heredity and endowment, he was fitted to take in life would, if thought of at all, have been only as a matter of regretful wonder on the part of parent or friend that it had not been adopted. I have had many similar examples in my practice. For instance, a woman, 22 years old, came to me suspecting that her daily headaches, persisting for many years, might be connected with eye troubles. It was, indeed, so. Her headaches disappeared, and other nervous derangements and choreic affections, and her general deterioration of health was changed as if by magic from the day her hyperopic astigmatism and insufficiency were relieved. But I also was interested to learn that in the past ten years one by one the intellectual and æsthetic occupations she had heroically undertaken had been laid aside, and everything dependent upon near vision, such as study, languages, painting, needlework, music, etc., etc., had been found so tiresome that her life had been wrenched from its natural order, and her whole mind had been regretfully turned to other exercises and uses.

Still another somewhat pathetic case came to me last week. Parents and teachers had for years stupidly scolded and punished a bright little girl ten years old, because of her inattention to studies and because of her petulance, nervousness, and insubordination. In fact, the child was quite choreic, and the pinched eyes and bent head told of eye-strain at once. Both eyes were astigmatic to the fearful degree of 5.50 D.—the highest astigmatic error I ever have met with. Who can doubt that her spectacles will have the most happy effect in changing the child's disposition, character, and the trend of her whole life, not only physically but in a psychological sense? There can be no doubt that this subtle and far-reaching cause—eye-strain—is at work everywhere to balk and blight. How many vocations and careers—intellectual, professional, or æsthetic—have been left unfilled, the natural aptitudes of character and endowment failing to reach their predestined fruition, because this subtle but effective enemy rendered it impossible? It is easy to pooh-pooh, and to talk glibly about the ridiculous conceits and exaggerations of the medical specialist. The pique of a dogmatist or hobby of a narrow-minded specialist is as nothing to the duty to truth and to humanity. The question remains, Is it so or not so? If my contention is true to the extent of the one-hundredth part of what I believe, it is a matter of the most profound significance for every parent, guardian, or general physician. Exactly their particular child or patient or friend may be undergoing an experience that is moulding the whole course of its future life, character, and influence upon the world. Liebreich contends that Turner's vision of the world and his pictures, and hence his æsthetic influence, was distorted by his astigmatism, and that if you wish to see a picture of his as it should have been painted, you must look at it through the cylindrical lens Turner should have worn to correct his astigmatism. If this be so, how sad it is to think Turner had not had such a lens! But however this may be, we cannot doubt that many a promising life has been switched, permanently crippled, into the side-tracks or lumber-yards of mercantile or humdrum life, that might have swept across continents, bearing its messages of intellectual honor and humanitarian service to all.

I cannot avoid the conclusion, let who will indulge his sneer and slur at "the weak vagaries of the specialist," that all young people who show any disinclination to literary work, or in whom such work produces any headache, ocular pains, or weariness and dimness—all such should at once

be sent to a competent oculist for examination as to the existence of refraction-errors or muscular insufficiencies.

119 S. Seventeenth St., Philadelphia.

ŒSOPHAGEAL STRICTURE.[1]

E. T. PAINTER, M.D.,
PITTSBURGH, PA

The patient, aged about thirty-eight, complained of difficulty in swallowing food and its regurgitation, both liquid and solid, and of inability to drink cold water or other cool drink. It was first noticed that food would not move on in response to the usual movements of deglutition, and that its onward progress was assisted by a few gentle raps on the back. This symptom first showed itself about six years ago. From this slight difficulty in the passage of solid food to the stomach, the patient gradually found herself compelled to subsist wholly on liquid foods, and these could be retained only when taken at a certain warm temperature. Neither water at ordinary temperature, nor cool drink of any sort, nor solid food, had entered the stomach in a period of years. She was emaciated and destitute of physical vigor.

An examination of the œsophagus with a bougie proved the existence of a band, which would resist the further progress of the instrument till the constriction *willed* to give way, when the bougie would easily slip into the stomach. Neither had the diameter of the bougie, nor the flexibility of a tube, nor force, seemed to have anything to do with passing through the constricting ring. Passage beyond the constriction could be made only when the ring was so disposed and inclined. There had been no pain or hemorrhage. There was no history of the introduction of a foreign body and its impaction, or of the swallowing of a strong acid or strong alkali. No aneurism was evident. There is no history of carcinoma. The constriction was sixteen inches from the lower incisors. Dysphagia and regurgitation, which prevented the patient retaining sufficient nourishing food, were the only symptoms given.

As drugs, massage, the passage of a flexible tube, and the Faradic current had failed to accomplish any good results, I resolved to give a thorough trial to the galvanic current locally applied, and that experiment I proceeded to make. I employed from six to ten cells of a galvanic chloride of silver battery, placing a sponge electrode joined to the negative pole in one hand, and an œsophageal electrode connected with the positive pole within the constricting ring. This electrode consisted of an ovoid shell, seven-sixteenths of an inch by three-fourths of an inch of perforated hard rubber, which could be unscrewed in the middle, and had sufficient space within for absorbent cotton, which came in contact with a small expanse of platinum, and that in turn was united by an insulated wire to the battery.

The battery used gives a current absolutely constant in character; and a water rheostat served to differentiate the strength of the current. My applications were made three times a week for a few weeks, then twice a week, each treatment lasting from six to twelve minutes.

At the termination of the first treatment the following occurrence took place. The current had passed for as long as I thought best, when, on attempting to withdraw the œsophageal electrode, it came easily, in response to my traction, for a few inches, when it was seized by a contraction of the œsophagus and there firmly held for a few seconds. This peculiar accident did not happen a second time. After each treatment the patient placed herself in a recumbent position for a half-hour. At the fourteenth visit the electrode was passed through and beyond the point of stricture without the knowledge of the patient, nor did I feel any sensation of opposition. At dinner, after the fifteenth application, the patient ate meat and bread and butter.

In about three months I made twenty-five applications, obtaining most decided improvement The contracting ring persists, but its irritability has disappeared. The patient eats, without regurgitation, of what others at the table partake, restricting herself in only one item of food—meat, which is cut fine for her. She drinks water and milk freely. For a time the stomach, unaccustomed to such foreign substances as bread and butter, strawberries, cheese, etc., made the patient aware of its change in function by dyspeptic disturbances.

The interesting points in this case are these: The ease with which a diagnosis of dyspepsia could have been made, its long existence, its obstinacy under manifold treatment, the continued presence of the stricture without its irritability, and the rapid change in character of the constriction under the influence of the galvanic current.

[1] A paper read at the meeting of the Allegheny County Medical Society, August 21, 1888.

FRACTURED PATELLA TREATED BY WIRING.[1]

BY J. J. BUCHANAN, M.D.,
PITTSBURGH, PA.

The patient is a German laborer, and his fracture was the result of direct violence, caused by the stroke of a three-hundred pound box which fell against his knee. He stated that the accident happened in the middle of the day of June 30. He continued to do his laboring work till evening, but on the following day found that he was unable to stand on the limb. I suppose that the blow broke the bone, but the capsule held together till evening. When he was brought to the hospital, five days afterward, the joint was considerably distended and the fracture easily recognized, but the lower fragment seemed to be very small. He was informed of the probable result by the use of external appliances, and the advantages as well as the risks attending the method by suture. With a full understanding of the circumstances he demanded the treatment which would give him the most useful limb, even though at some slight risk to his life. I accordingly operated on the eleventh day after the injury.

The most scrupulous precautions against sepsis were taken. Instruments and appliances were put through the same course of preparation as for laparotomy. Continuous irrigation with 1-2500 sublimate solution was employed, and the transverse incision was made to the full extent of the rent in the capsule. The lower fragment was not larger than a chestnut. The capsule was much lacerated, and a number of narrow shreds hung into the joint; the joint contained a great deal of clotted blood and bloody fluid. The joint was thoroughly washed out and all loose pieces and ragged ends and edges of capsule were cut away with scissors. The fractured surfaces were refreshed by the vigorous use of a curette. A single hole was drilled through each fragment, the drill entering about three-eighths of an inch from the line of fracture, and emerging at the cartilaginous border of the fractured surface. As a motive power for the drill, I used the dental engine, which was kindly supplied and manipulated for me by Dr. Charles Phillips, a dentist of this city. A silver wire of No. 24 gauge was passed. An incision was made into the lower part of the joint on the outside of the limb and a rubber drain inserted, the inner extremity barely entering the joint. The silver wire was then twisted firmly, which brought the fragments into place, and the ends of the wire were turned down between the edges of the apposed fragments. The capsule was closely united over the whole length of the rupture with the continuous catgut suture.

Interrupted silkworm-gut stitches were used for the soft parts down to the capsule. Sublimated dressings and a posterior splint completed the work. At the expiration of the third day the drain was exposed and withdrawn. The primary dressing was removed at the end of a week, when the wound of the soft parts was found to be soundly healed and the skin stitches were all taken out. The progress of the case was aseptic and of course absolutely devoid of pain and discomfort. At the end of four weeks the patient was allowed out of bed, and at the end of five and a half weeks all dressings were removed and he was allowed to walk upon the limb with the aid of crutches. At the end of six and a half weeks he was permitted to rely on a cane without any support to the limb. When I last examined him four or five days ago, palpation of the patella gave no evidence of its ever having been fractured. The range of motion is not yet great, but is rapidly increasing and will, I doubt not, be completely restored.

There is no question that the treatment of fractured patella by external retentive apparatus is extremely unsatisfactory. An occasional case of close ligamentous union encourages the surgeon, but the great majority of cases have a half-inch or more of separation which gradually increases; a large proportion have refracture or rupture of the ligament and almost all have limbs of greatly impaired usefulness.

On the contrary wiring, when it succeeds, as it usually does, is said to leave the patient with bony union and with a freely movable joint. It certainly is the most speedy and least troublesome of all methods of treatment. I myself think it is destined to be the treatment of the future. As our methods of securing asepsis of operative wounds become more certain and our skill in applying them increases, so will the patella suture become better established. In the present condition of the science the mortality of this operation is slight, but it still exists. I think it will be reduced practically to zero. As things now are I think the advisability of the operation in any particular case should

[1] A paper read at the meeting of the Allegheny County Medical Society, August 21, 1888.

depend upon the wishes of the patient and the skill of the operator in securing asepsis. If the patient is unwilling or his attendant lacks the technical skill for rigid antisepsis the operation should not be thought of. On these points I can do no better than to quote the words of Dr. Frank W. Rockwell, of Brooklyn: "Finally, I believe that as long as this form of fracture is treated by the ordinary methods employed, just so long will the present unsatisfactory results continue to obtain; and I believe it to be the duty of the surgeon, in any given case, at least to give his patient the benefit of deciding for himself whether he will have wiring done or not, and in event of his selecting the operation, to do it at the earliest proper time, if capable of performing a thoroughly aseptic operation, since I believe that by so doing he will obtain the best results in the largest number of cases"

To the same effect has Dr. Lewis S. Pilcher, also of Brooklyn, expressed himself: "The whole principle of exposing the patella and refreshing the fragments and bringing them together is the outgrowth of the antiseptic principle, and to a very considerable extent it may be considered one of the most difficult achievements of antiseptic work. Now it seems to me that, in expressing an opinion upon the justifiability of an operation of this kind, we ought to qualify it somewhat in this way: That a surgeon who has become a master of the practice of antisepsis, as well as the principles, and who is able to control with certainty the conditions which surround his patient, would be justified in opening the knee-joint in a recent case of fracture of the patella and bringing the fragments together; but I doubt very much whether, excepting under such circumstances, it would be justifiable."

—In consequence of the criticisms passed upon the Board of Health in the matter of the death of Richard A. Proctor, the astronomer, particularly by George W. Wilson, a friend of the deceased, who declared that he did not die of yellow fever, an autopsy was held on the body by Drs. Prudden and Biggs, pathologists to the Board of Health. These physicians report that, while decomposition was so far advanced that it was impossible to arrive at a definite conclusion as to the cause of death, there was nothing to indicate that the cause of death was not yellow fever. This can hardly be regarded as a demonstration, and the diagnosis still rests in some doubt.

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Special Meeting, August 21, 1888.

W. M. Brinton, M.D., President, in the Chair.

Dr. T. W. Shaw read the Report of Committee on the death of Dr. Thomas J. Gallaher.

Fatal Case of Typhoid Fever.

Dr. J. C. McMullen reported a case of typhoid fever. The case proceeded favorably until upon the seventh day milk was given the patient. This was followed by a high temperature and a rapid pulse. Vomiting supervened, and the patient died upon the thirteenth day. The value of milk as a food in typhoid fever was then discussed.

Dr. Wood thought it a case in which milk was injurious, and he considered the feeding of milk a frequent mistake. Some patients have idiosyncrasies that make milk harmful. Again, it is a proper food late but not early in the disease. Good digestion of milk is often insured when whey, or half milk and whey, is given.

Dr. J. M. Batten thought the case a malignant one, and its termination in no manner influenced by the milk administered. The temperature should have been controlled by cold baths instead of by quinine, as was done.

Dr. W. D. Kearns said that beef tea is proper food when milk is rejected, and that high temperature is not to be feared to the extent formerly believed. He never exhibited antipyretics in his practice, but stimulated the patient, giving quinine and carbonate of ammonia.

Dr. Stewart called attention to the utility of butter-milk where milk was rejected.

Dr. McCann thought that, as a rule, typhoid fever is badly treated. The patient is over-medicated and over-fed. Milk, because of its decomposition in the intestinal canal, is not a safe food. During this process the poisonous animal alkaloids are formed, and they, acting through the nervous system, induce relapses, high temperatures, and other unfavorable events. He uses antifebrine and sponge baths for high temperature, and prefers gruels, vegetable juices, and beef tea to milk.

A Case of Œsophageal Stricture.[1]

Dr. Duff presented a case of

Purpura Simplex.

A child had been suffering from diarrhœa for some three or four weeks, and had received home remedies which would check it for a time, but it had returned in a few days. The child had been in this condition until the time I saw it. Upon seeing it I discovered at once it was a case of what I would term purpura simplex. There were spots of all grades upon its back and extremities, some very livid and some a pale yellow color as they were disappearing, all being, with one exception, about the size of a finger-nail. One on the back was perhaps the size of a silver dollar. I gave the child some bismuth and pepsin, and in the interim between the doses of pepsin I had it take two drops of aromatic sulphuric acid. It improved in a few days and then took a slight relapse, so far as the diarrhœa was concerned; but the spots continued to disappear. It got so well that I didn't see it for several days. I was sent for perhaps a week afterward and notified that the diarrhœa had returned, with vomiting. I saw it and continued the same treatment with the addition of lime-water. The child improved again for three or four days, when I dismissed it, as I thought it comparatively well. Its mother took sick within a few days after this, and I attended her for two or three days, when my attention was drawn to the child as suffering very materially from its teeth, as it was biting its gums and crying a great deal. I examined its teeth, or its gums, and found them very much swollen. I examined especially in the region of the upper canine teeth. I thought to relieve it by scoring the gum; this was in the evening, about five or six o'clock. I scored over one of the canine teeth and went home, thinking nothing of it. About daylight I was called to the house, and found the child lying in bed, the mother's clothing all over blood, and the bed bloody, and the child pulseless. I administered restoratives and worked with it for some time until it revived somewhat. In the afternoon I saw it again, and the purpuric spots had reappeared on its back and there was some hemorrhage from the bowels, as well as hemorrhage from the bladder. The child died the next morning. I may say that it is not strictly a case of hæmophilia. I examined the histories on the father's and mother's side, and there was no history of hemorrhage in the family, with the exception of the father, who has frequently had severe hemorrhages from the nose. There is no history of tubercular trouble in either branch.

Dr. J. J. Buchanan read a paper on

Fractured Patella Treated by Wiring.[1]

Dr. Murdoch, in opening the discussion on Dr. Buchanan's paper, said: The case is certainly a very interesting one, and, as far as I know, it is the first case in this city in which the patella has been wired, either for simple or compound fracture. Every one who has had much practice in fractures of the patella has found some difficulty in keeping the fragments in position. Long before the use of antisepsis, or any attempt thereat, in order to hold the bones in position, Malgaigne's hooks were used; they are to be had yet, I suppose, in any of our surgical instrument stores. They were used in such cases successfully, but owing to the fact, probably, that the wound was not made aseptic, the operation was abandoned as leading to inflammation and disease in the joint.
